1 PRISMA checklist

PRISMA NMA Checklist of Items to Include When Reporting A Systematic Review Involving a Network Meta-analysis

Section/Topic	Item #	Checklist Item	Reported on Page #
TITLE			
Title	1	Identify the report as a systematic review <i>incorporating a network meta-analysis (or related form of meta-analysis)</i> .	Title, abstract, page 5
ABSTRACT			
Structured summary	2	<p>Provide a structured summary including, as applicable:</p> <p>Background: main objectives</p> <p>Methods: data sources; study eligibility criteria, participants, and interventions; study appraisal; and <i>synthesis methods, such as network meta-analysis</i>.</p> <p>Results: number of studies and participants identified; summary estimates with corresponding confidence/credible intervals; <i>treatment rankings may also be discussed. Authors may choose to summarize pairwise comparisons against a chosen treatment included in their analyses for brevity</i>.</p> <p>Discussion/Conclusions: limitations; conclusions and implications of findings.</p> <p>Other: primary source of funding; systematic review registration number with registry name.</p>	Page 3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known, <i>including mention of why a network meta-analysis has been conducted</i> .	Page 4
Objectives	4	Provide an explicit statement of questions being addressed, with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	Page 4
METHODS			
Protocol and registration	5	Indicate whether a review protocol exists and if and where it can be accessed (e.g., Web address); and, if available, provide registration information, including registration number.	Page 5
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale. <i>Clearly describe eligible treatments included in the treatment network, and note whether any have been clustered or merged into the same node (with justification)</i> .	Page 5
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	Page 5
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Appendix 2.1
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	Page 5 and appendix 5
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	Page 6
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	Page 5
Geometry of the network	S1	Describe methods used to explore the geometry of the treatment network under study and potential biases related to it. This should include how the evidence base has been graphically summarized for presentation, and what characteristics were compiled and used to describe the evidence base to readers.	Page 5, network plots figure 1 and appendix 8

Risk of bias within individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	Page 6 and appendix 14
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means). <i>Also describe the use of additional summary measures assessed, such as treatment rankings and surface under the cumulative ranking curve (SUCRA) values, as well as modified approaches used to present summary findings from meta-analyses.</i>	Page 6 and appendix 4
Planned methods of analysis	14	Describe the methods of handling data and combining results of studies for each network meta-analysis. This should include, but not be limited to: <ul style="list-style-type: none"> • <i>Handling of multi-arm trials;</i> • <i>Selection of variance structure;</i> • <i>Selection of prior distributions in Bayesian analyses; and</i> • <i>Assessment of model fit.</i> 	Page 6 and details of statistical analysis in appendix 4
Assessment of Inconsistency	S2	Describe the statistical methods used to evaluate the agreement of direct and indirect evidence in the treatment network(s) studied. Describe efforts taken to address its presence when found.	Page 6 and appendix 9
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	Page 6 and appendix 13
Additional analyses	16	Describe methods of additional analyses if done, indicating which were pre-specified. This may include, but not be limited to, the following: <ul style="list-style-type: none"> • Sensitivity or subgroup analyses; • Meta-regression analyses; • Alternative formulations of the treatment network; and • Use of alternative prior distributions for Bayesian analyses (if applicable). 	Page 6
RESULTS†			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	Page 7 and appendix 5
Presentation of network structure	S3	Provide a network graph of the included studies to enable visualization of the geometry of the treatment network.	Figure 1 and appendix 8
Summary of network geometry	S4	Provide a brief overview of characteristics of the treatment network. This may include commentary on the abundance of trials and randomized patients for the different interventions and pairwise comparisons in the network, gaps of evidence in the treatment network, and potential biases reflected by the network structure.	Page 7-10, network plots figure 1 and appendix 8; Characteristics of included studies and Risk-of-bias assessment in appendix 6 and 14
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Appendix 6.3
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment.	Page 7, appendix 14.3
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: 1) simple summary data for each intervention group, and 2) effect estimates and confidence intervals. <i>Modified approaches may be needed to deal with information from larger networks.</i>	Forest plots of pairwise meta-analyses for each outcome in appendix 8
Synthesis of results	21	Present results of each meta-analysis done, including confidence/credible intervals. <i>In larger networks, authors may focus on comparisons versus a particular comparator (e.g. placebo or standard care), with full findings presented in an appendix. League tables and forest plots may be considered to summarize pairwise comparisons.</i> If additional summary measures were explored (such as treatment rankings), these should also be presented.	Page 7-8, league tables and forest plots (figure 2-5 and appendix8)
Exploration for inconsistency	S5	Describe results from investigations of inconsistency. This may include such information as measures of model fit to compare consistency and inconsistency models, <i>P</i> values from statistical tests, or summary of inconsistency estimates from different parts of the treatment network.	Page 7 and appendix 9
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies for the evidence base being studied.	Page 7,10, appendix 13
Results of additional analyses	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression analyses, <i>alternative network geometries studied, alternative choice of prior distributions for Bayesian analyses</i> , and so forth).	Page 7, appendix 11-12

DISCUSSION			
Summary of evidence	24	Summarize the main findings, including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy-makers).	Page 9
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review level (e.g., incomplete retrieval of identified research, reporting bias). <i>Comment on the validity of the assumptions, such as transitivity and consistency. Comment on any concerns regarding network geometry (e.g., avoidance of certain comparisons).</i>	Page 10 and specific issues in appendix 15
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	Page 9-10
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review. This should also include information regarding whether funding has been received from manufacturers of treatments in the network and/or whether some of the authors are content experts with professional conflicts of interest that could affect use of treatments in the network.	Funding/Support in Declaration section

PICOS = population, intervention, comparators, outcomes, study design.

* Text in italics indicates wording specific to reporting of network meta-analyses that has been added to guidance from the PRISMA statement.

† Authors may wish to plan for use of appendices to present all relevant information in full detail for items in this section.

2 Search strategy

2.1 Search strings and dates of searches

We searched the register of the Cochrane Schizophrenia Group's Study-Based Register of trials.

Following the methods from Cochrane¹, the Information Specialist compiles this register from systematic searches of major resources and their monthly updates (unless otherwise specified):

1. MEDLINE;
2. Embase;
3. Allied and Complementary Medicine (AMED);
4. Cumulative Index to Nursing and Allied Health Literature (CINAHL);
5. PsycINFO;
6. PubMed;
7. US National Institute of Health Ongoing Trials Register ClinicalTrials.gov;
8. World Health Organization International Clinical Trials Registry Platform (www.who.int/ictrp);
9. ProQuest Dissertations and Theses A&I and its quarterly update;
10. Chinese databases (Chinese Biomedical Literature Database, China Knowledge Resource Integrated Database, and Wanfang) and their annual updates until the end of 2016.

The register also includes handsearches and conference proceedings (see Group's website: <http://schizophrenia.cochrane.org/register-trials>). It does not place any limitations on language, date, document type or publication status.

Further information about the register has been published by Shokraneh et al²⁻⁵.

The search string of the first search in the Cochrane Schizophrenia Group's Study-Based Register of trials (27/04/2020) was:

(*Amisulpride* OR *Aripiprazole* OR *Asenapine* OR *Benperidol* OR *Brexipiprazole* OR *Cariprazine* OR *Chlorpromazine* OR *Clopenthixol* OR *Clozapine* OR *Flupentixol* OR *Fluphenazine* OR *Fluspirilene* OR *Haloperidol* OR *Iloperidone* OR *Levomepromazine* OR *Loxapine* OR *Lumateperone* OR *Lurasidone* OR *Molindone* OR *Olanzapine* OR *Paliperidone* OR *Penfluridol* OR *Perazine* OR *Perphenazine* OR *Pimozide* OR *Quetiapine* OR *Risperidone* OR *Sertindole* OR *Sulpiride* OR *Thioridazine* OR *Tiotixene* OR *Trifluoperazine* OR *Ziprasidone* OR *Zotepine* OR *Zuclopenthixol*) in Intervention Field of STUDY

The update search was conducted in PubMed (14/06/2021) with the following search string:

(amisulpride OR aripiprazole OR asenapine OR benperidol OR brexipiprazole OR cariprazine OR chlorpromazine OR clopenthixol OR clozapine OR flupentixol OR fluphenazine OR fluspirilene OR haloperidol OR iloperidone OR levomepromazine OR methotriptazine OR loxapine OR lumateperone OR lurasidone OR molindone OR olanzapine OR paliperidone OR penfluridol OR perazine OR perphenazine OR pimozide OR quetiapine OR sertindole OR sulpiride OR thioridazine OR thiothixene OR trifluoperazine OR ziprasidone OR zotepine OR zuclopenthixol OR risperidone) AND random*

Filter: Publication date: From 2020/4/1 onwards

2.2 Survey to inform the choice of the searched first-generation antipsychotic drugs

As the aim of our network meta-analysis is to provide a comprehensive overview on long-term metabolic side effects of antipsychotic drugs, we did not apply any restrictions in form of administration and included all newer antipsychotics developed in the last decades (formerly called second-generation antipsychotics (SGAs)) as well as a selection of the most important older antipsychotics.

The selection of the older antipsychotics, formerly called first-generation antipsychotics, was informed by a survey of international schizophrenia experts⁶. In a simple survey 56 international experts were asked to select 10 formerly called first-generation antipsychotics that they found most important (for whatever reason) out of an alphabetically ordered list of at that time 52 antipsychotics listed by the “WHO Collaborating Centre for Drug Statistics” (http://www.whocc.no/atc_ddc_methodology/who_collaborating_centre/). Although the survey has methodological limitations in the selection of experts and statistical evaluation, it provides some guidance on which older antipsychotics are still clinically relevant. The 15 drugs with the most votes were chosen (chlorpromazine, clopenthixol, flupenthixol, fluphenazine, haloperidol, levomepromazine, loxapine, molindone, perazine, perphenazine, pimozide, sulpiride, thioridazine, trifluoperazine and zuclopenthixol). Benperidol and fluspirilene are frequently used in Germany and were therefore added to the selection because the project was sponsored by the German Ministry of Education and Research. Penfluridol and tiotixene were also supplemented because we knew from Cochrane reviews that many studies have been conducted, unlike for other older antipsychotics.

Of note, our list of included antipsychotics contains all antipsychotics listed in the WHO list of essential medicines⁷.

3 Protocol

The protocol of this systematic review with network meta-analysis was registered in Prospero (CRD42020175414) and published in BMC Systematic Reviews⁸.

3.1 Changes with respect to the protocol

In our protocol we planned a meta-regression on antipsychotic dose. However, due to methodological concerns regarding an appropriate model for this meta-regression, we decided to perform instead a post-hoc sensitivity analysis excluding doses of antipsychotics at the lower and upper ends of the International Consensus Study on Antipsychotic Dosing⁹ to investigate the robustness of our primary results.

Additionally, we conducted one post-hoc sensitivity analysis of the primary outcome in which we pooled oral and LAI applications of the same drug to increase statistical power and connectivity.

4 Details of the data analysis

4.1 Measures of treatment effect

The effect size for continuous outcomes was mean difference (MD) as weight, glucose and lipid parameters were always measured on the same scale. In some cases units were converted: for weight, pounds were converted to kg and, for lipid and glucose parameters, mmol/l was converted to mg/dl.

If both data from observed cases and imputation methods to account for participants lost to follow-up (last-observation-carried forward, mixed-model-of-repeated-measurements) were available, we preferred the latter. (Data of observed cases for the primary outcome were also evaluated in a sensitivity analysis.)

If the original study investigators presented only the observed number of participants with the event, we assumed that participants lost to follow-up i.e., without reporting an event while they were observed in the study, would not have had the event should they have stayed in the study for the total follow-up.

If information on standard deviations (SDs) was missing, we derived SDs from standard errors, confidence intervals, t statistics, or P values for differences in means as described in Section 6.5.2.3 of the Cochrane Handbook for Systematic Reviews¹⁰. When no such information was available in the individual study, we derived SDs from those of the other studies using a validated imputation technique¹¹.

The effect size for the dichotomous outcome weight gain was odds ratio (OR) and its 95% credible interval (CrI). OR are preferred to risk ratios (RR) for meta-analyses due to their mathematical properties^{12,13}.

4.2 Statistical details for network meta-analysis and meta-regression models

When the consistency assumption was deemed reasonable, Bayesian network meta-analyses (NMA) and network meta-regression-analyses (NMR) were fitted as hierarchical model.

Bayesian NMA and NMR were fitted in R using the BUGSnet package¹⁴ and network meta-regression analyses using self-programmed routines with the rjags package¹⁵, respectively. We accounted for the correlations induced by multi-arm studies by employing multivariate distributions.

The heterogeneity (variability in relative treatment effects within the same treatment comparison) was measured with the tau-squared (the variance of the random effects distribution). The heterogeneity variance was assumed common across the various treatment comparisons.

Network meta-analysis:

For the model without covariates we fitted a random effects consistency model using Placebo as reference. All models were run using three chains and 10 000 iterations after an initial burn-in of 1 000.

Network meta-regressions:

In the network meta-regression models, we set

$\theta_{i,k}^* = \theta_{i,k} + \beta_k \times x_i$ where x_i indicates the continuous covariate (e.g. study duration) in study i ,

or

$\theta_{i,k}^* = \theta_{i,k} + \beta_{1,k} \times x_{1,i} + \dots + \beta_{j,k} \times x_{j,i}$, in case the covariate is categorical (e.g. gender) and x_i indicates the frequency of j category (e.g. proportion of women) in i study.

If the study includes placebo as a reference, then $\beta_k = B$ (or $\beta_{j,k} = B$) is the increase in the effect of treatment k versus placebo for one unit of increase in the covariate. If study i involves only active treatments, we assume $\beta_k = 0$ (or $\beta_{j,k} = 0$).

Priors:

We assume vague normal priors $N(0, 10^4)$ for the parameters u_i and d_B, d_C, d_D, \dots and B . For heterogeneity we employed a uniform distribution $\tau \sim U(0,5)$.

Convergence:

All models were run using two chains and 100 000 iterations after an initial burn-in of 1 000; a thinning of 2 was used. This was deemed appropriate based on autocorrelation plots and the visualization of the chain convergence.

5 Characteristics and references of included studies

5.1 Overview of characteristics of studies with usable data

Characteristic	Value
N studies with usable data	137
N participants	35007
N antipsychotic drugs used	31
N studies using double blind design (%)	96 (70%)
N studies using enriched design (%)	26 (19%)
N studies sponsored by pharmaceutical companies (%)	108 (79%)
Years when studies were published	1967 to 2020
Median average age of participants (IQR, range)	38.93 (35.25 to 41.36, 15.35 to 69.45) years
Median percentage of women (IQR, range)	37.06 (29.23 to 42.75, 0 to 100) %
Median duration of studies (IQR, range)	45 (26 to 52, 16 to 104) weeks
Median dose in olanzapine equivalents used (IQR, range)	14 (11.41 to 17.78, 2.61 to 33.01) mg/day
Median baseline weight (IQR, range)	76.55 (72.03 to 81.60, 53.51 to 103.66) kg

Table of summary characteristics of studies with usable data for any analysis. N = number, IQR = Interquartile Range.

5.2 Overview of characteristics of studies reporting the primary outcome “weight gain”

Characteristic	Value
N studies with usable data	110
N participants	29215
N antipsychotic drugs used	28
N studies using double blind design (%)	81 (74%)
N studies using enriched design (%)	22 (20%)
N studies sponsored by pharmaceutical companies (%)	95 (86%)
Years when studies were published	1970 to 2018
Median average age of participants (IQR, range)	38.93 (35.51 to 41.05, 15.35 to 69.45) years
Median percentage of women (IQR, range)	37.06 (30.06 to 42.21, 15 to 100) %
Median duration of studies (IQR, range)	48 (26 to 52, 16 to 104) weeks
Median dose in olanzapine equivalents used (IQR, range)	14 (11.3 to 17.35, 2.61 to 32.86) mg/day
Median baseline weight (IQR, range)	76.55 (71.76 to 81.46, 53.51 to 103.66) kg

Table of summary characteristics of studies with usable data for any analysis. N = number, IQR = Interquartile Range.

5.3 Characteristics and references of specific studies with usable data

Study	Year of publication	Blinding	Duration (wks)	Diagnostic term (diagnostic criteria)	Intervention	Application	Dosing interval	Dose mean and range (mg)	N (randomized)	% female	Age mean (y)	Baseline weight mean (kg)
Abuzzahab 1977a ¹⁶	1980	double blind	156	Schizophrenia (Clinical Diagnosis)	Fluphenazine	oral	daily	12.7 (3-30)	31	76%	34.8	-

6 Transitivity assessment

We included only RCTs in participants with schizophrenia or related disorders (such as schizophreniform or schizoaffective disorders) with a study duration > 13 weeks (3 months) and with doses within the target to maximum doses of the International Consensus Study on Antipsychotic Dosing⁹. We did not apply restrictions in stage of the disease (acute episode; maintenance phase), participant age, gender or setting (inpatients or outpatients) because we deem the development of metabolic side effects rather independent of these factors. Based on these inclusion criteria, we assumed that participants in the selected studies were equally likely to be randomized to any of the antipsychotics investigated. To assess transitivity of the network as recommended by the Cochrane handbook¹⁰, we visually compared the distribution of potential effect modifiers across comparisons including baseline weight, age, gender, ethnicity, life-time exposure to antipsychotics (if not available duration of illness was used as a proxy), study duration and antipsychotic dose. The box-plots used are presented below.

Summary of transitivity assessment:

The assessment of transitivity is performed by comparing the distribution of potential effect modifiers for each comparison and is limited when only one or very few studies per comparison are available. Overall, we judged that there are no clear violations of the transitivity assumption considering the following specific reflections:

In the boxplot for baseline weight it can be seen that for most of the comparisons the baseline weight was between 70 and 90 kg. Four studies showed a lower baseline weight. These studies were conducted in Asian and/or younger populations or in women in 1970. For these populations lower values of baseline weight can be expected. Nevertheless the frequency of overweight (i.e. the distribution of BMI) can be similar compared to the study population of other studies (BMI was not evaluated because it was not available for many studies).

The median mean age observed in the comparisons ranged between 15 to 52 years with most of the comparisons between 30 and 45 years. The distribution of proportion women ranged for most comparisons between 0.25 and 0.5 with four studies above and four studies below this range. As stated above we did not apply restrictions in these classical population characteristics age and gender because we assumed that these do not affect the development of metabolic side-effects to an important extent.

However, different ethnicities may have a different propensity to develop metabolic side effects. Therefore, we explored exemplary the distribution of proportion of white and black ethnicity within the included studies. The provided information in the original studies did not allow a more detailed evaluation of ethnicities. Since the influence of ethnicity has not yet been conclusively clarified we further examined the role of ethnicity in network meta-regression analyses.

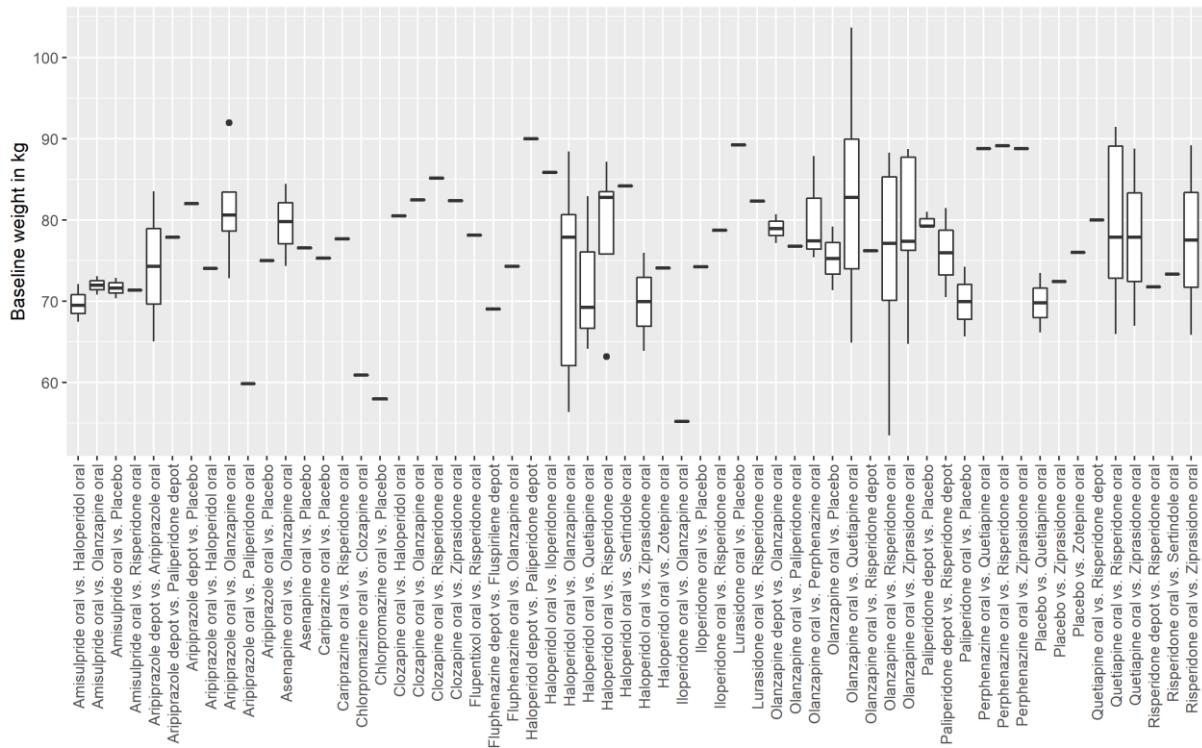

We expected metabolic side effects to occur rather independent of population characteristics with the exception of previous antipsychotic exposure that could have led to antipsychotic-induced weight gain before study participation. The average life-time exposure to antipsychotics was around 10 years for most comparisons. 7 of 137 studies were conducted in participants with minimal prior antipsychotic exposure. Those studies were excluded in a sensitivity analysis.

Regarding study duration, we only included trials with a duration > 13 weeks (3 months) because we were focussing on mid- to long-term side effects. The median study duration of most comparisons was between 6 and 12 months.

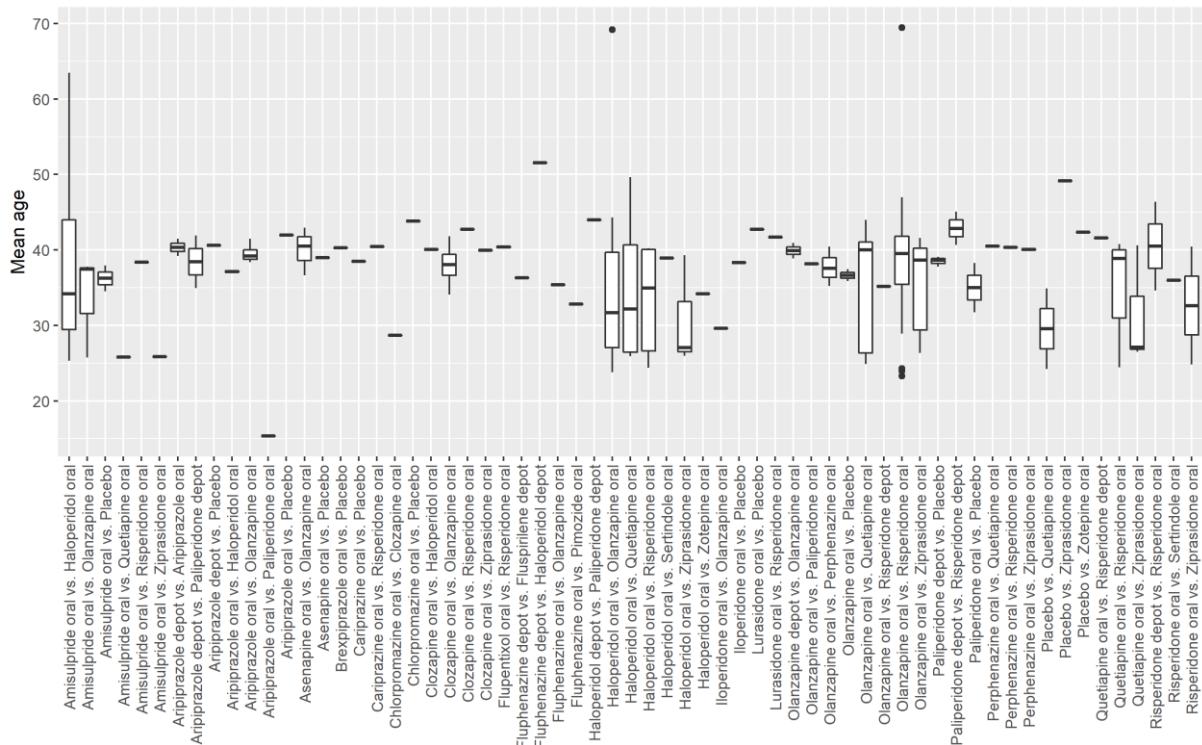

Concerning antipsychotic dosing, we included only study arms with doses within the target to maximum range according to the International Consensus Study on Antipsychotic Dosing⁹. Only for special populations such as patients with first episode or primarily negative symptoms for which clinically different dosing regimens are recommended, we included lower doses. These study arms were excluded in a sensitivity analysis, which did not change the results. Two comparisons (aripiprazole oral vs. haloperidol oral and clozapine oral vs. haloperidol oral, see box-plots) with one study each had a median mean dose above 30 mg/d olanzapine equivalent (maximum dose range for olanzapine according to the International Consensus Study on Antipsychotic Dosing⁹). However, the original doses used in the studies (30 mg/d aripiprazole oral in Kasper 2003 and 401 mg/d clozapine in Volavka 2002) were below the maximum dose of the International Consensus Study on Antipsychotic Dosing⁹. Therefore, the conversion in olanzapine equivalents leads to these increased doses in olanzapine equivalents.

Boxplots per study design and population characteristic:

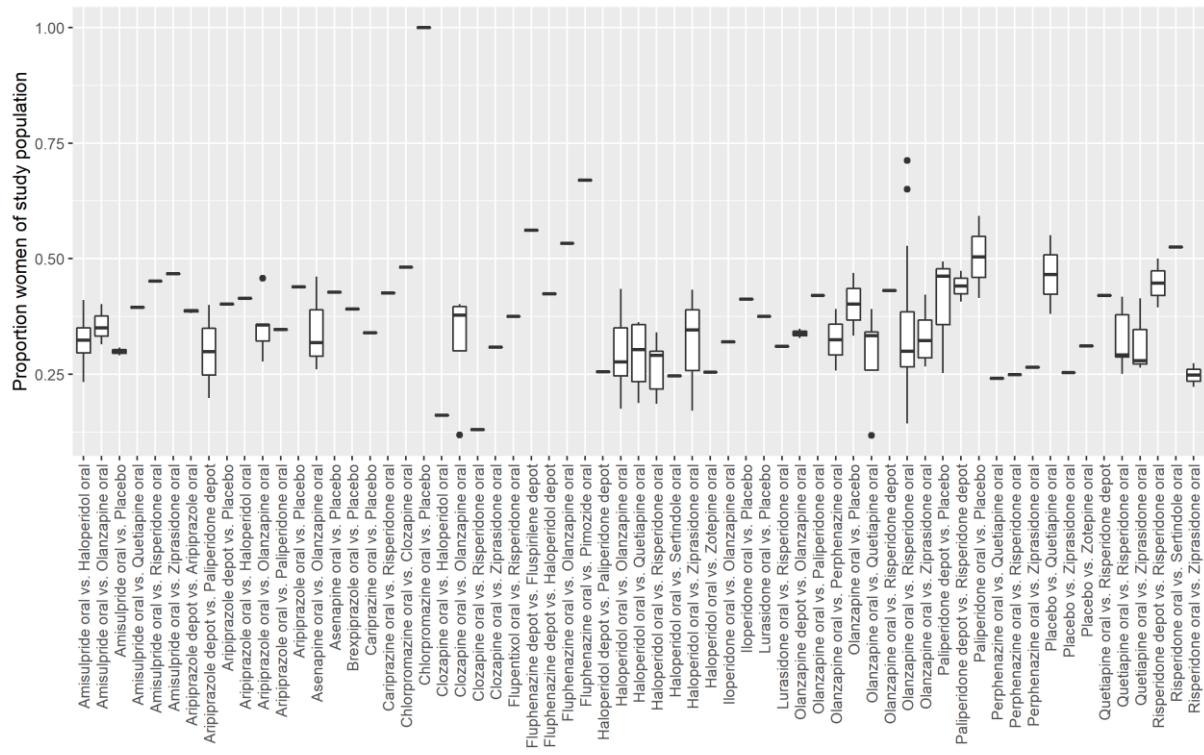

6.1 Baseline weight

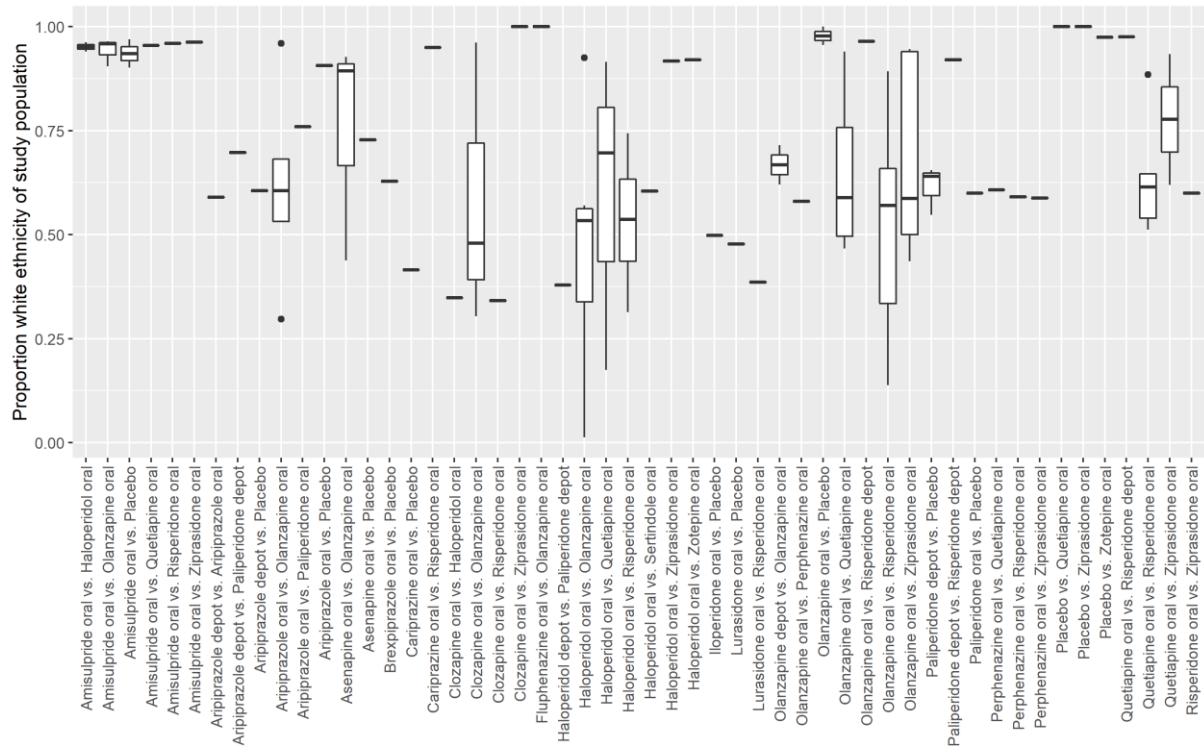

6.2 Mean age of participants

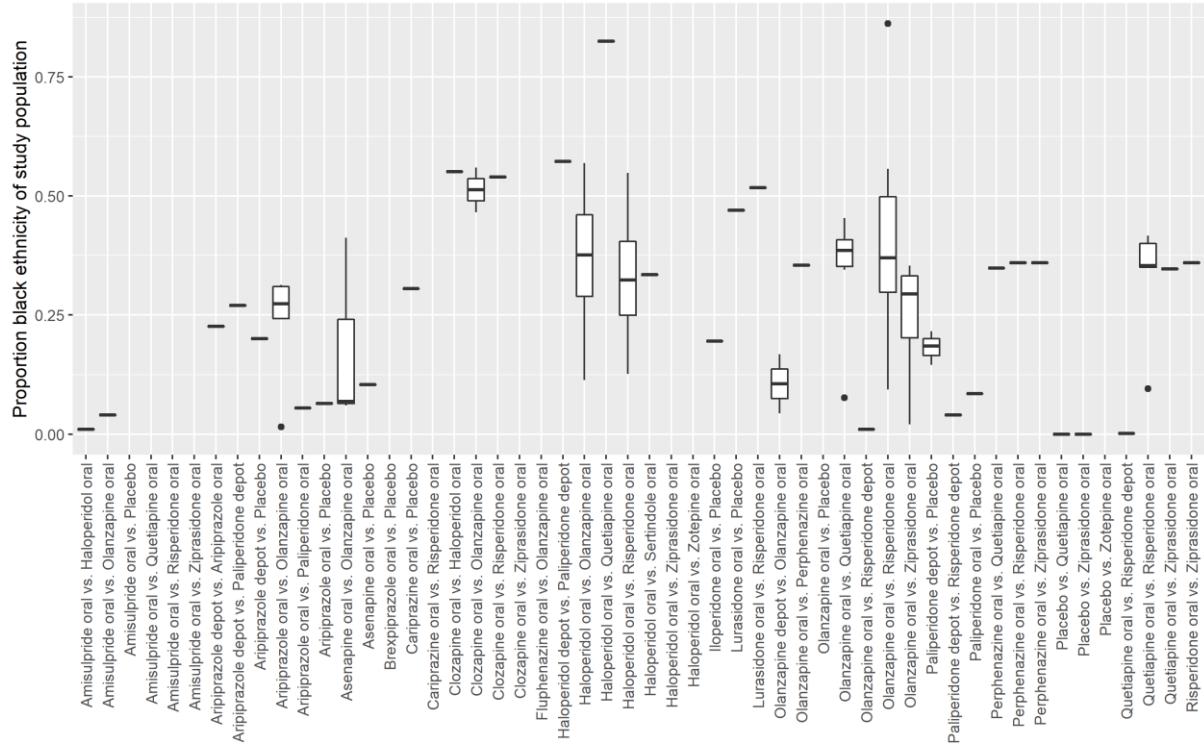

6.3 Proportion women of study participants

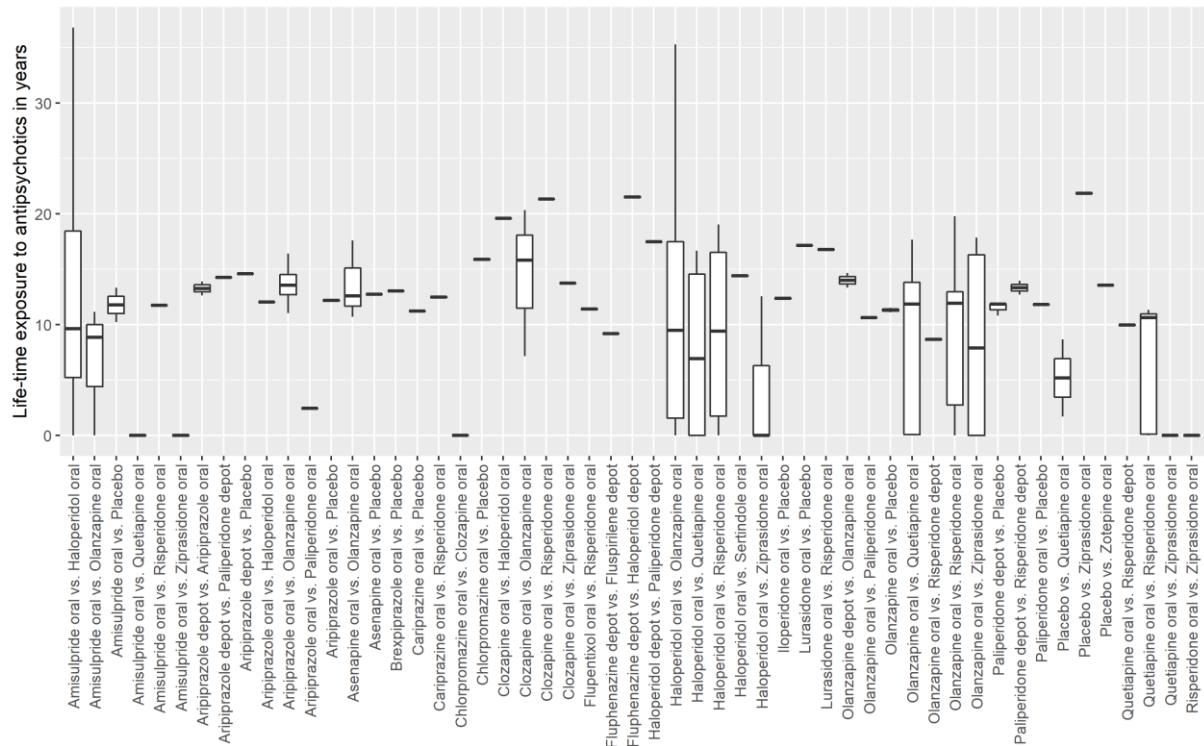

6.4 Proportion of white and black ethnicity in study population

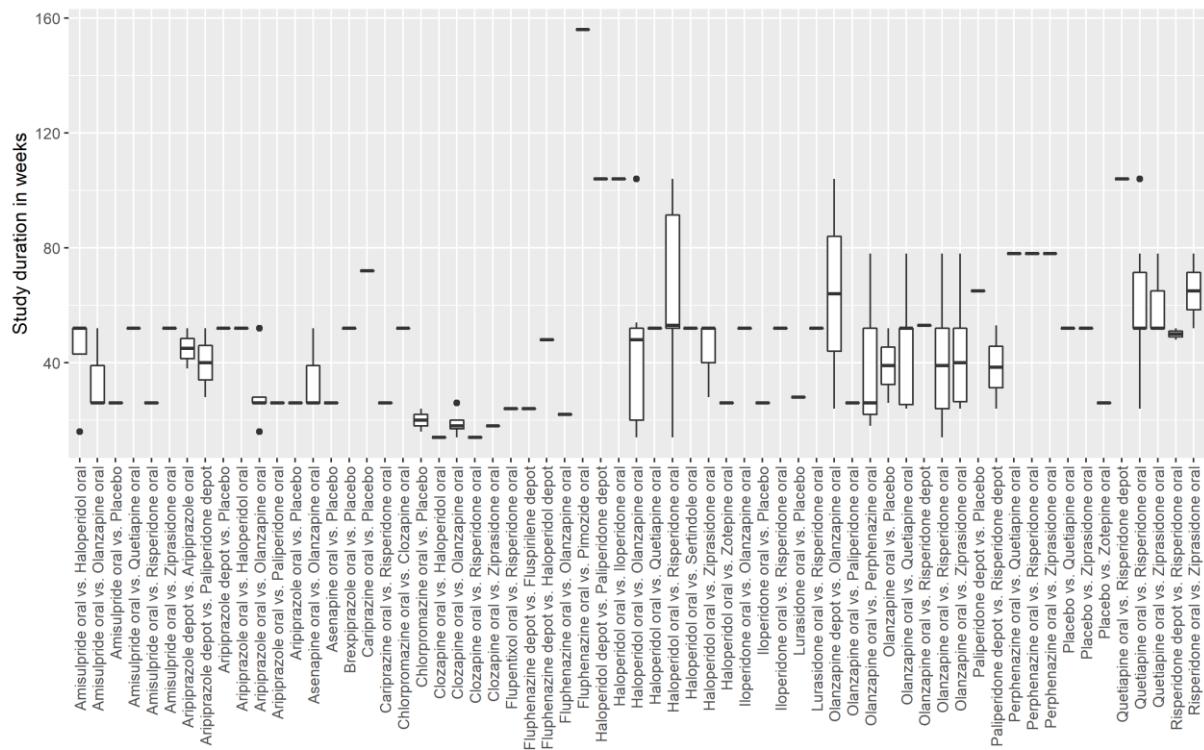

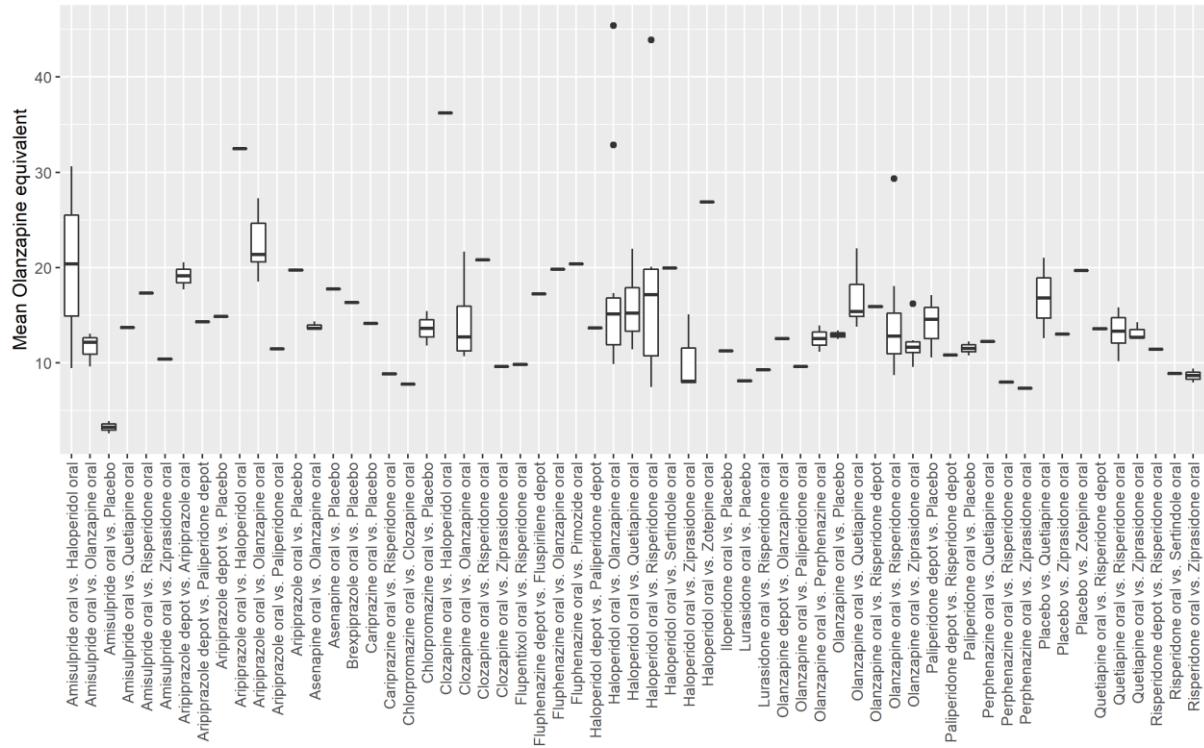

6.5 Life-time exposure to antipsychotics (if not available duration of illness used as a proxy)

6.6 Study duration

6.7 Antipsychotic dose in olanzapine equivalents based on scientific equivalents

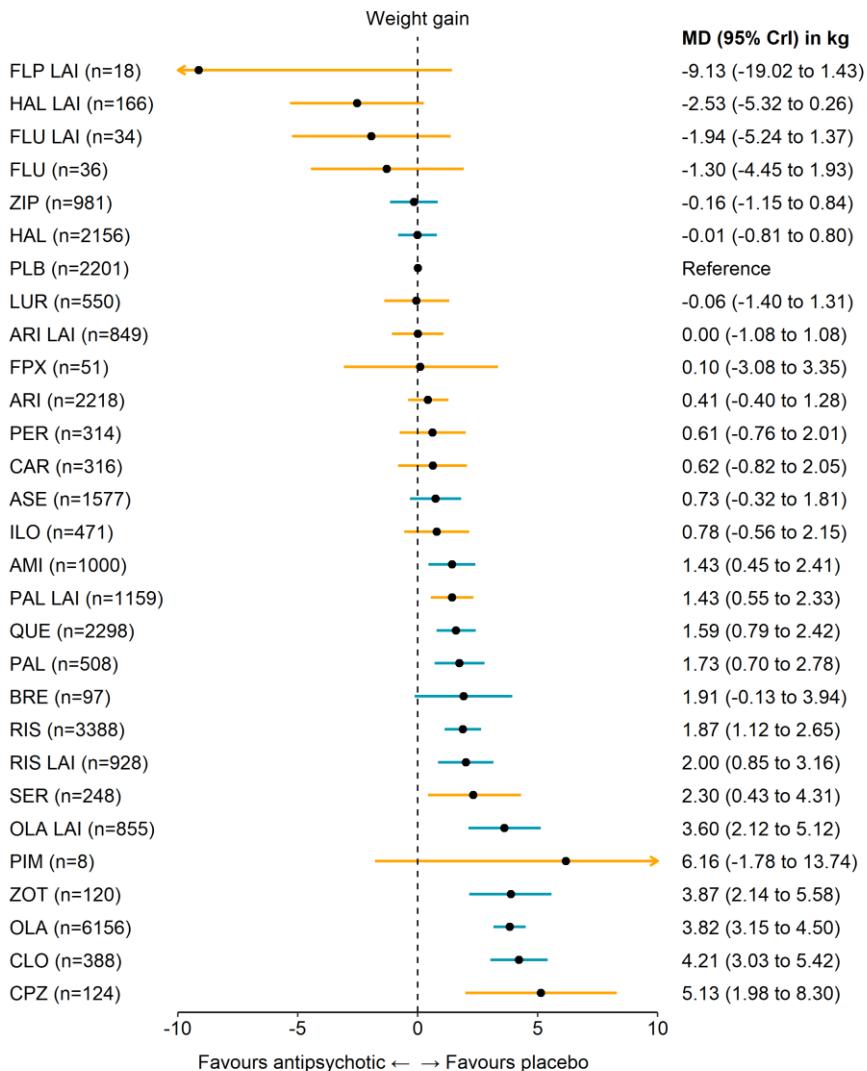

7 Additional results of the network meta-analysis of the primary outcome “weight gain” and secondary outcomes

For each outcome we present below (in this order, if not shown in the manuscript)

- Network plot
- Forest-plot of results of network meta-analysis (reference intervention placebo)
- League-table of results of network meta-analysis (presenting results for all comparisons)
- Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

7.1 Primary outcome “weight gain”

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

Network meta-analysis estimates of treatment effect of each drug vs. placebo reported as mean differences (MDs) and 95% credible intervals (CrIs) with their confidence rating assessed with the Confidence in Network Meta-Analysis (CINeMA) tool with blue representing moderate confidence, and orange representing low confidence. The order of treatments is according to surface under the cumulative ranking curve (SUCRA) ranking. The direction of the effect is indicated below the x-axis.

Abbreviations: n=number of patients, MD=mean difference, 95%-CrI =95% credible interval, LAI=long-acting injectable, AMI – amisulpride, ARI – aripiprazole, ASE – asenapine, BRE – brexpiprazole, CAR – cariprazine, CLO – clozapine, CPZ – chlorpromazine, FLP – fluspirilene, FLU – fluphenazine, FPX – flupentixol, HAL – haloperidol, ILO – iloperidone, LUR – lurasidone, OLA – olanzapine, PAL – paliperidone, PER – perphenazine, PIM – pimozide, PLB – placebo, QUE – quetiapine, RIS – risperidone, SER – sertindole, ZIP – ziprasidone, ZOT – zotepine.

The order of treatments is according to SUCRA ranking. Results of the network-meta-analysis are presented in the left lower half and results of pairwise meta-analyses in the right upper half. Each cell provides the mean difference and the corresponding 95% CrI of a comparison (treatment in column vs treatment in row for the network meta-analysis; treatment in row vs treatment in column for the pairwise meta-analysis). Bold print indicates 95% CrIs excluding the point of no effect. For the results of the network meta-analysis, the background colours of the cells reflect confidence in the estimates, with blue representing moderate confidence, orange representing low confidence, and red representing very low confidence.

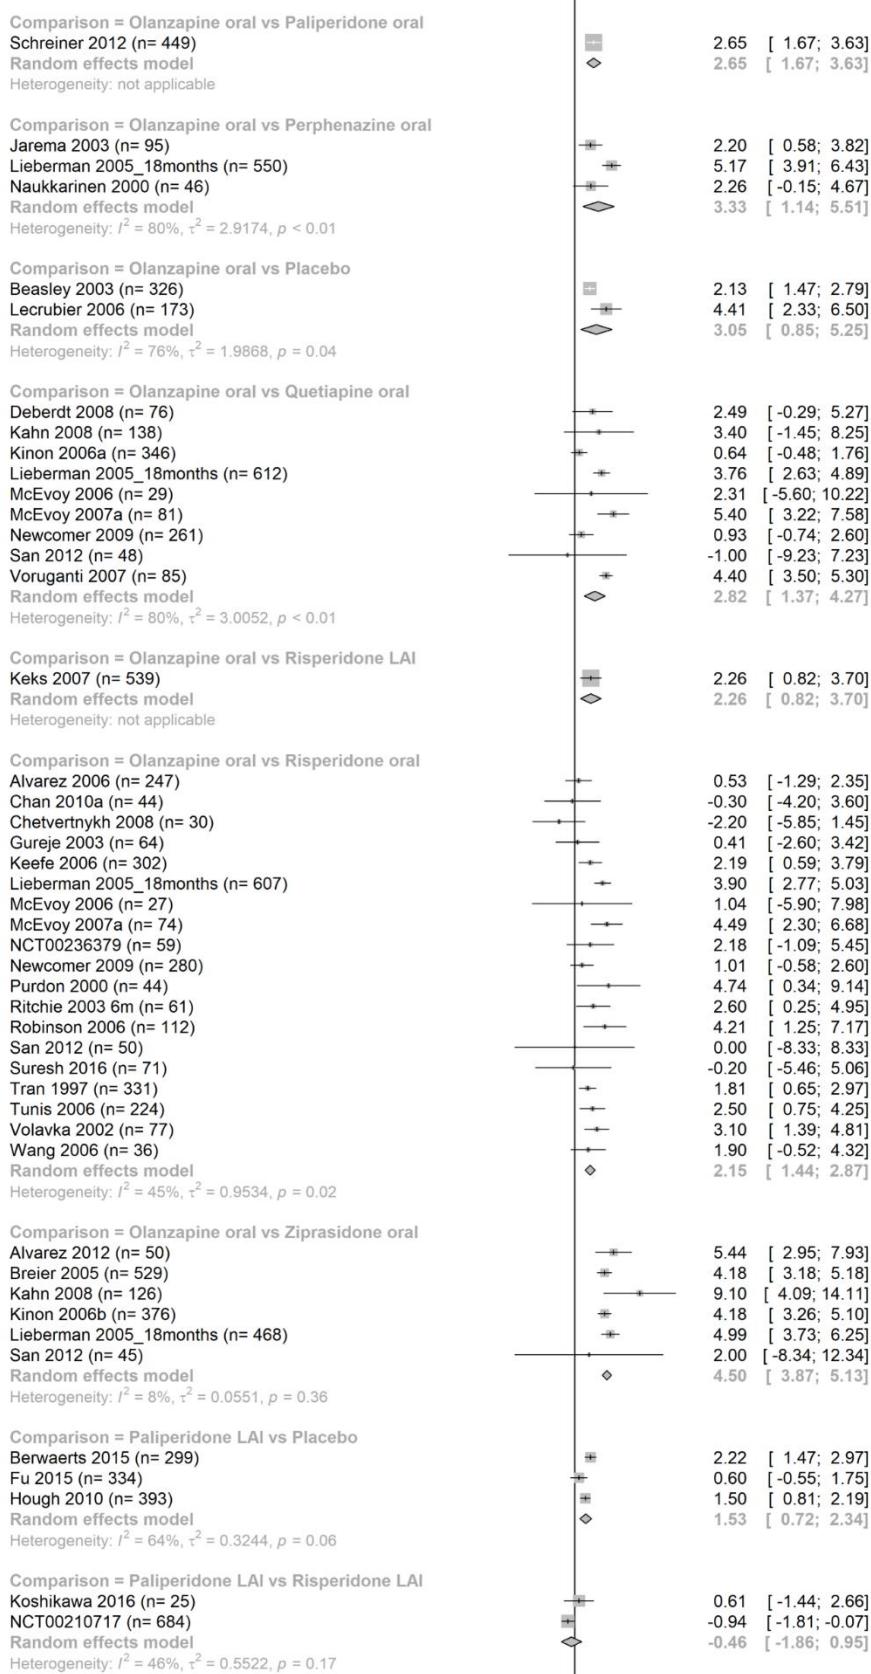

Abbreviations: CrI=credible interval. LAI=long-acting injectable, NA=not available, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

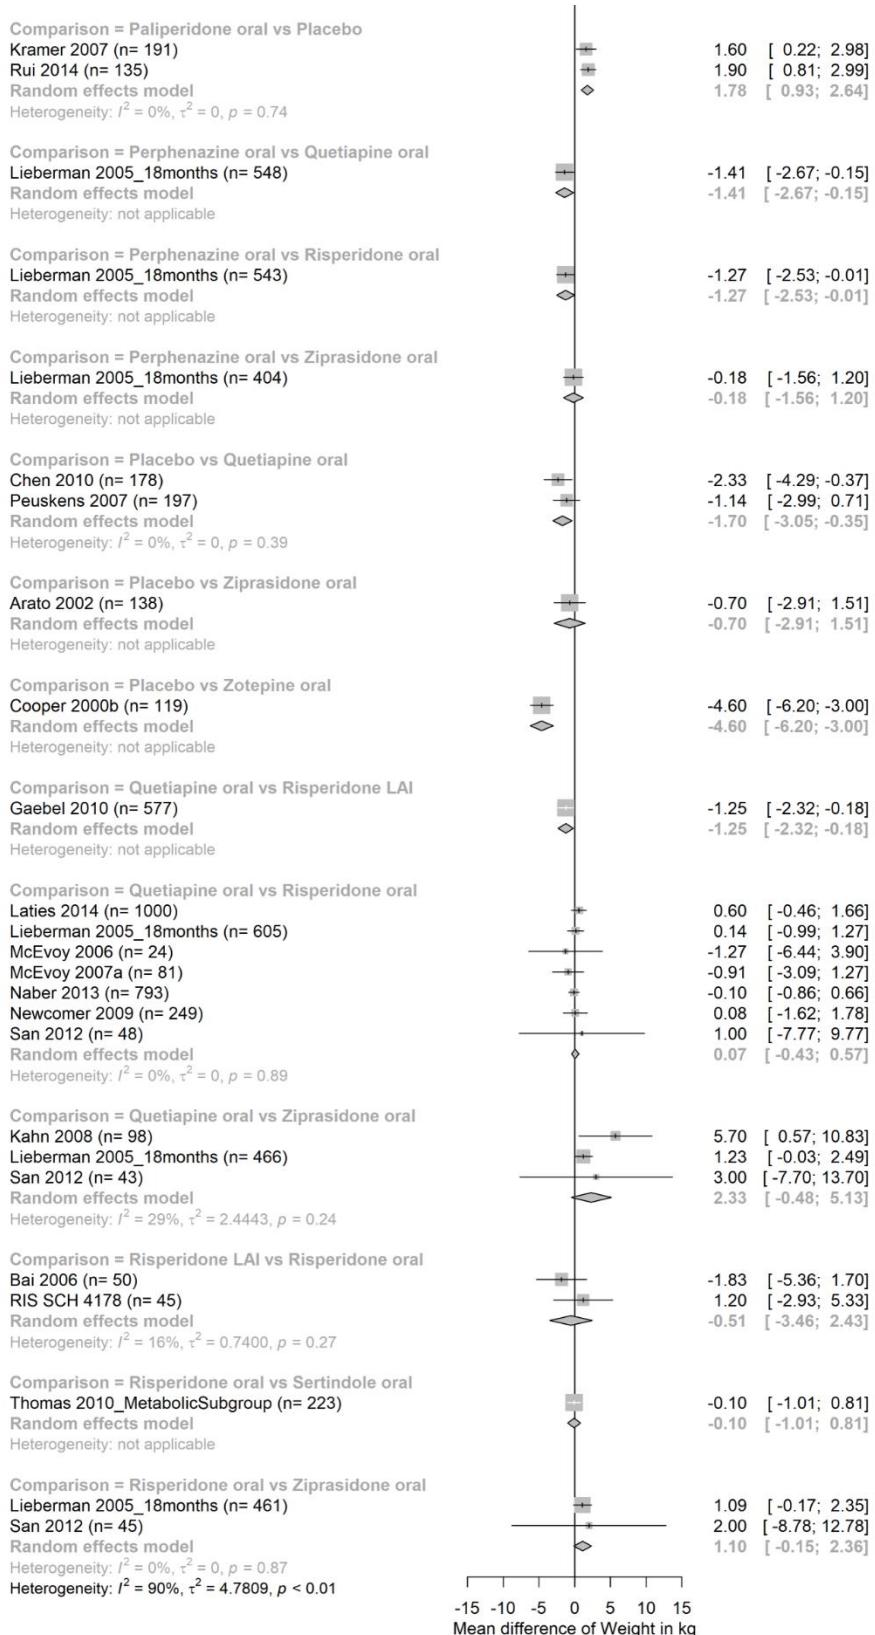

Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

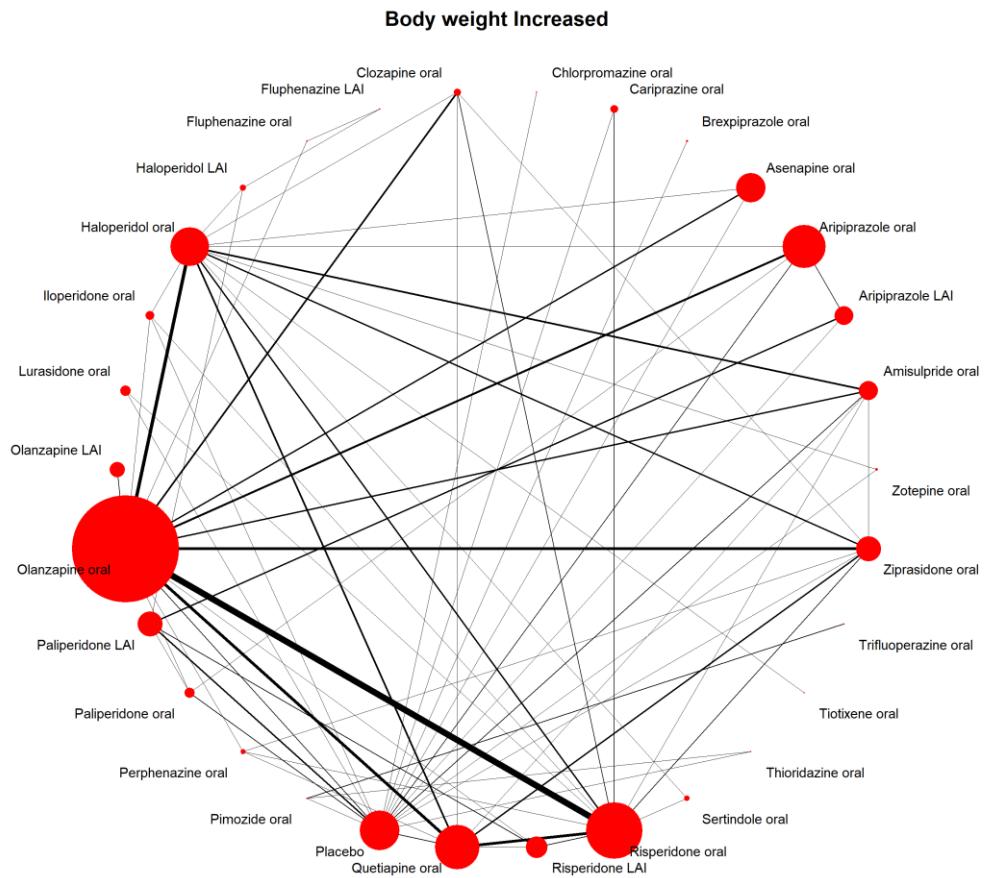

Pairwise meta-analyses are ordered by comparison investigated (in alphabetical order) and a summary effect size is calculated by pairwise meta-analyses of all studies of a specific comparison. The type of effect size measure is mean difference (MD).

Abbreviations: MD=mean difference, 95% CI=95% confidence interval, LAI=long-acting injectable.

7.2 Number of participants with weight gain

106 studies on 29 antipsychotics with 31519 participants included reported on dichotomous weight gain.

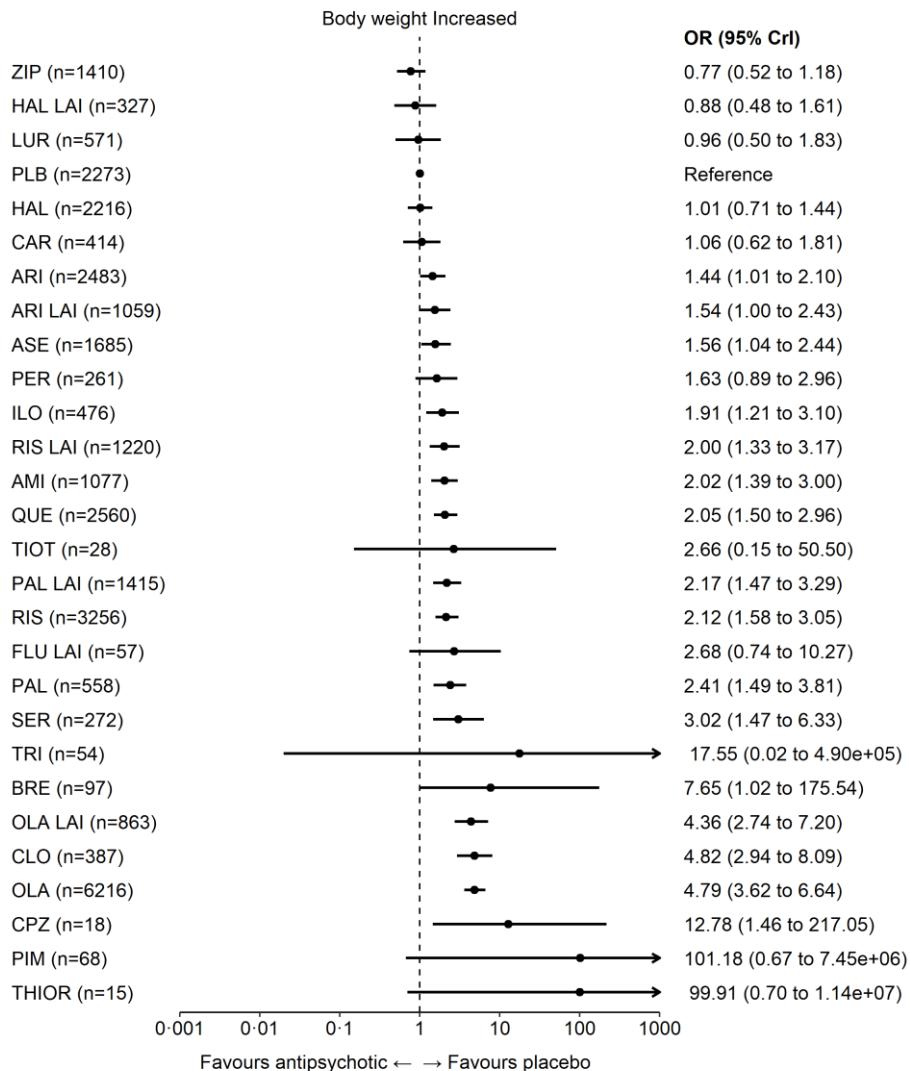

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Abbreviations: LAI=long-acting injectable.

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as odds ratio (OR) and 95% credible interval (CrI). Order of treatments is according to SUCRA ranking. The direction of the effect is indicated below the x-axis. For better presentability fluphenazine and zotepine are not presented in the graph (see comment below).

Abbreviations: n=number of patients, OR=odds ratio, 95%-CrI =95% credible interval, LAI=long-acting injectable, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

Comments to the secondary outcome number of participants with weight gain

The results of fluphenazine oral and zotepine oral are not shown in the graph above because the analyses yielded extreme but unreliable estimates. For fluphenazine oral the odds ratio was 0.00 (CrI 0.00 to 0.07) and for zotepine oral 2493.60 (CrI 26.34 to 616036.25). The reason was the presence of no events in at least one intervention in all studies of these drugs which prevents proper modeling. No events occurred in 61 patients treated with fluphenazine oral in two studies. 11 events occurred in 122 patients treated with zotepine oral in two studies however there were no events in the comparator interventions.

Overall, the ranking of the outcome number of participants with weight gain was very similar to the primary outcome. Notable exceptions were fluphenazine LAI which did, however, not significantly differ from placebo in both continuous weight gain and number of participants with weight gain (the change in the ranking and the uncertainty of the effect estimate is probably influenced by the 0 events in fluphenazine oral to which it was compared, see above and network plot). Additionally, the ranking of cariprazine and risperidone LAI differed slightly as compared to continuous data.

Order of treatments is according to SUCRA ranking. Results of the network meta-analysis are presented in the left lower half and results of pairwise meta-analyses in the right upper half. Each cell provides the effect estimate as odds ratio (OR) and the corresponding 95% credible interval (95% CrI) of a comparison (left lower half: treatment in column versus treatment in row; right upper half: treatment in row versus treatment in column). Bold print indicates 95% CrIs excluding the point of no effect.

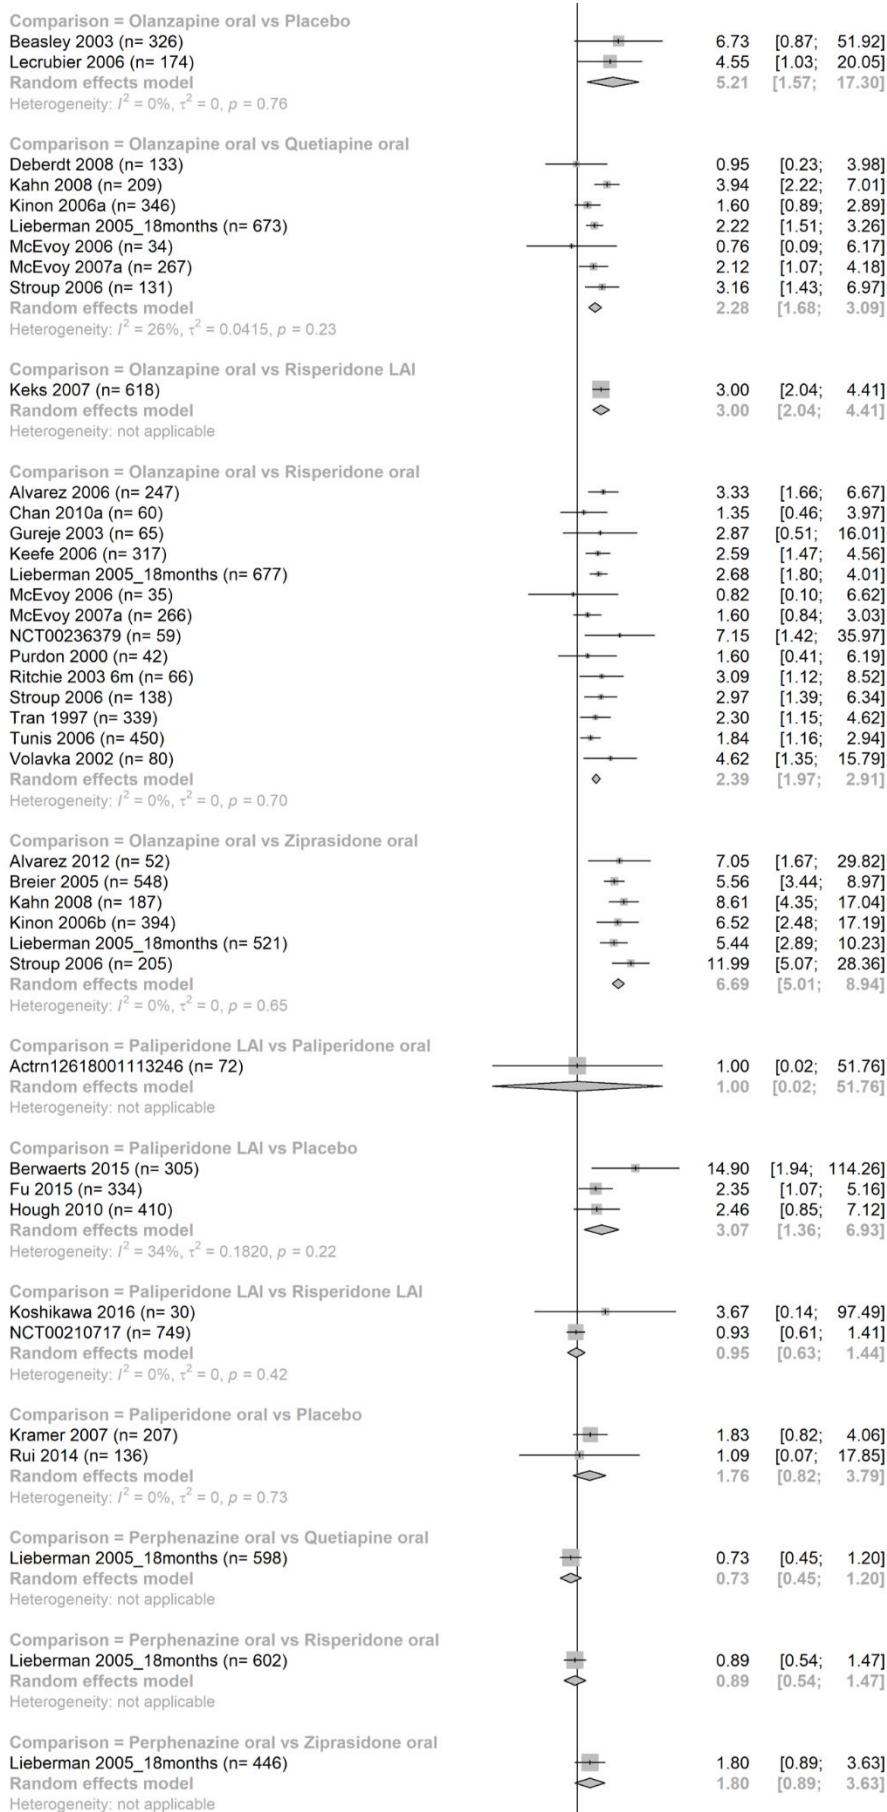

Abbreviations: NA=Not available, LAI=long-acting injectable, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

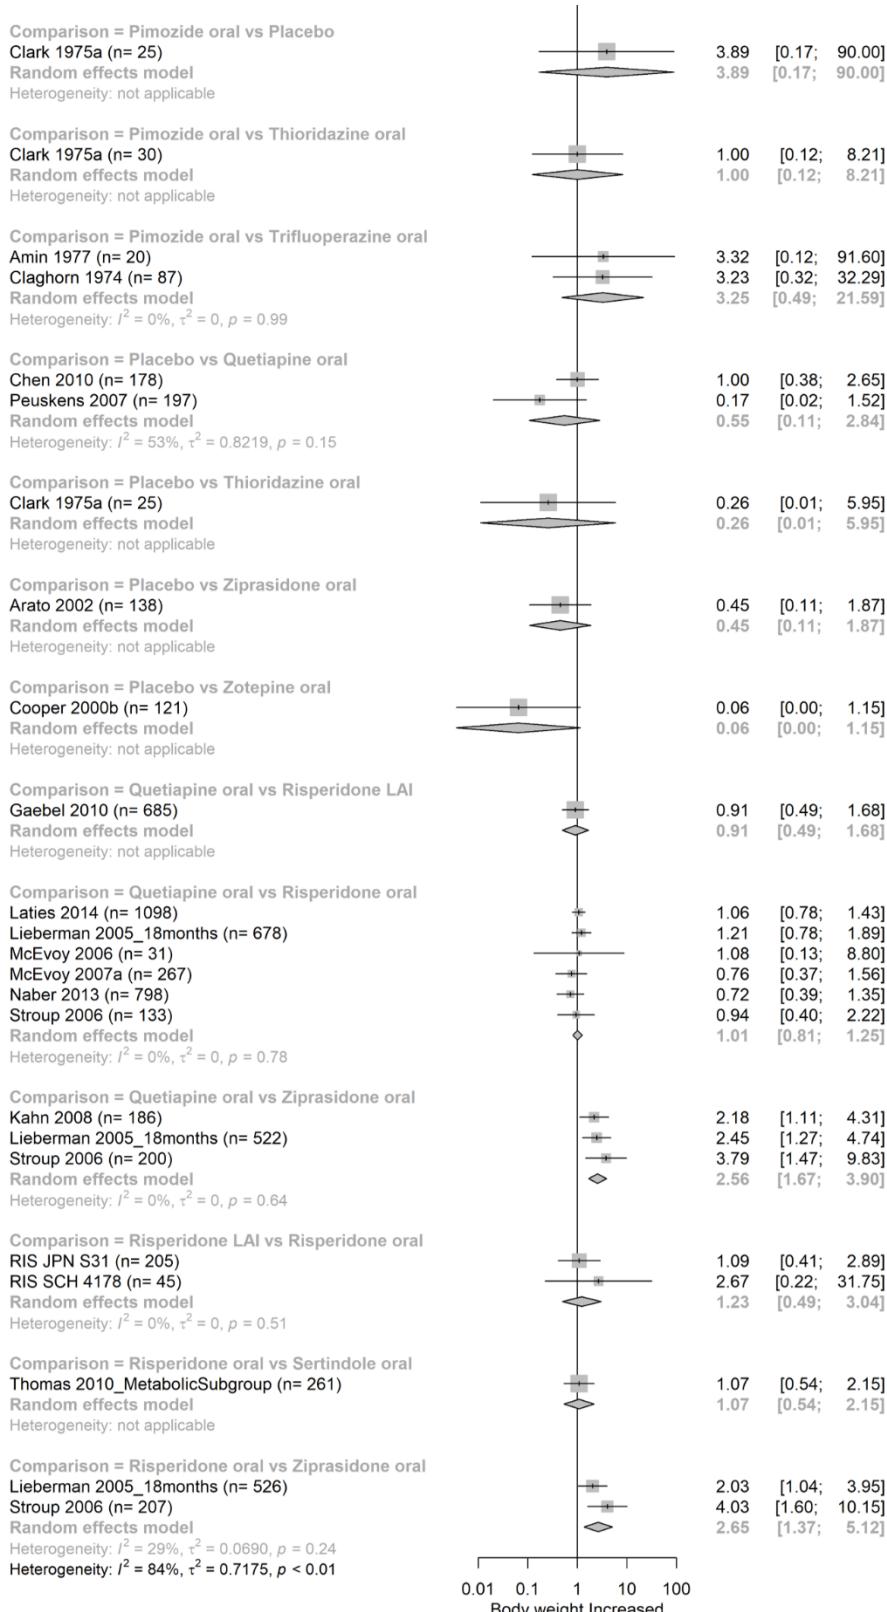

Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

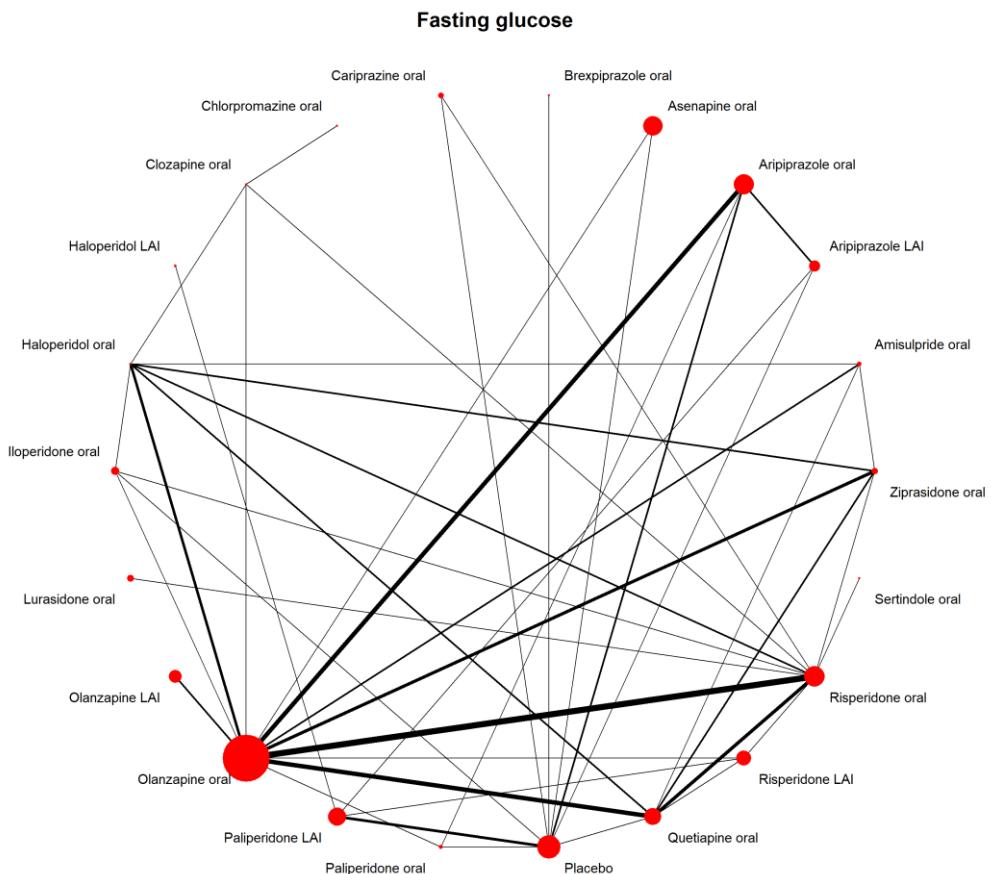

Pairwise meta-analyses are ordered by comparison investigated (in alphabetical order) and a summary effect size is calculated by pairwise meta-analyses of all studies of a specific comparison. The type of effect size measure is odds ratio (OR).

Abbreviations: OR=odds ratio, 95% CI=95% confidence interval, LAI=long-acting injectable.

7.3 Fasting glucose

50 studies on 21 antipsychotics with 17992 participants included reported on fasting glucose.

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Abbreviations: LAI=long-acting injectable

Order of treatments is according to SUCRA ranking. Results of the network meta-analysis are presented in the left lower half and results of pairwise meta-analyses in the right upper half. Each cell provides the effect estimate as mean difference (MD) and the corresponding 95% credible interval (95%CrI) of a comparison (left lower half: treatment in column versus treatment in row; right upper half: treatment in row versus treatment in column). Bold print indicates 95% CrI excluding the point of no effect.

Abbreviations: NA=Not available, LAI=long-acting injectable, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

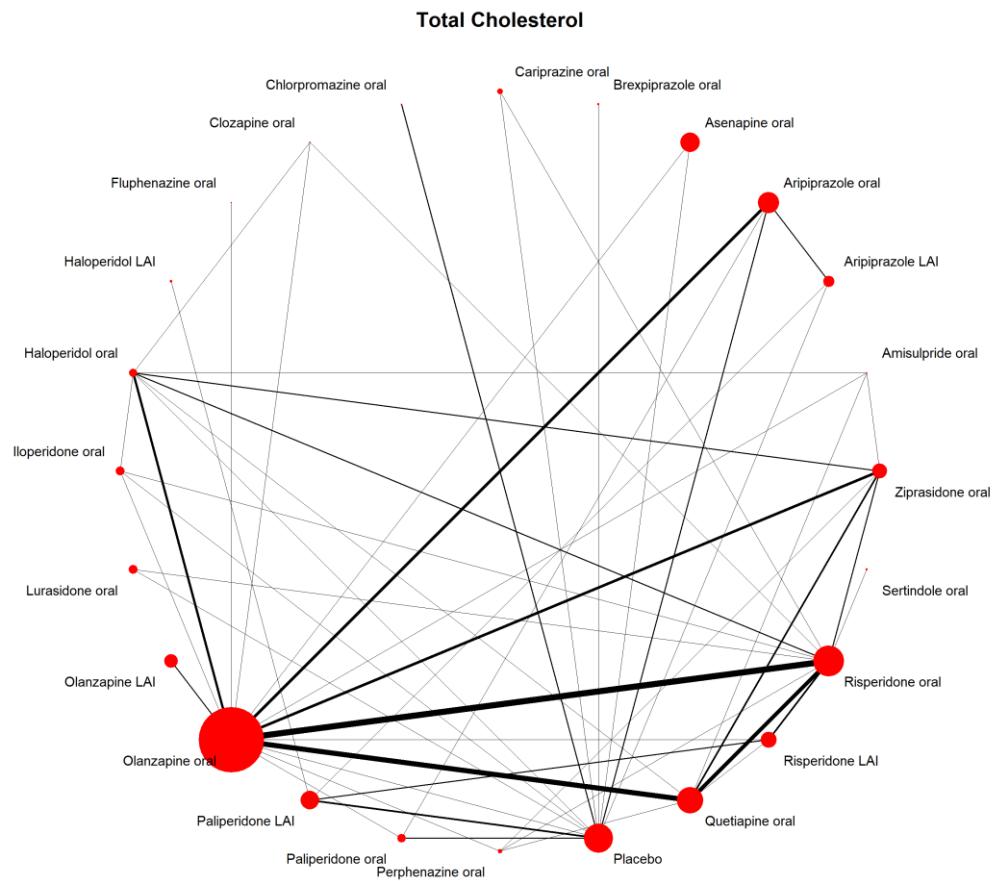

Pairwise meta-analyses are ordered by comparison investigated (in alphabetical order) and a summary effect size is calculated by pairwise meta-analyses of all studies of a specific comparison. The type of effect size measure is mean difference (MD).

Abbreviations: MD=mean difference, 95% CI=95% confidence interval, LAI=long-acting injectable.

7.4 Total cholesterol

63 studies on 23 antipsychotics with 18012 participants included reported on total cholesterol.

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Abbreviations: LAI=long-acting injectable.

Order of treatments is according to SUCRA ranking. Results of the network meta-analysis are presented in the left lower half and results of pairwise meta-analyses in the right upper half. Each cell provides the effect estimate as mean difference (MD) and the corresponding 95% credible interval (95%CrI) of a comparison (left lower half: treatment in column versus treatment in row; right upper half: treatment in row versus treatment in column). Bold print indicates 95% CrI excluding the point of no effect.

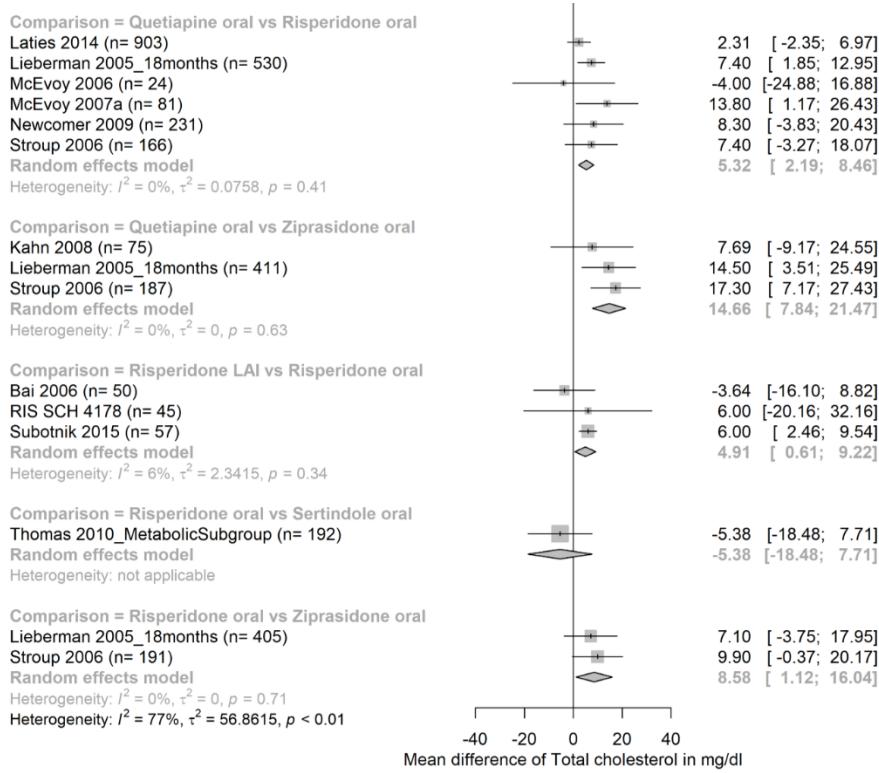

Abbreviations: NA=Not available, LAI=long-acting injectable, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

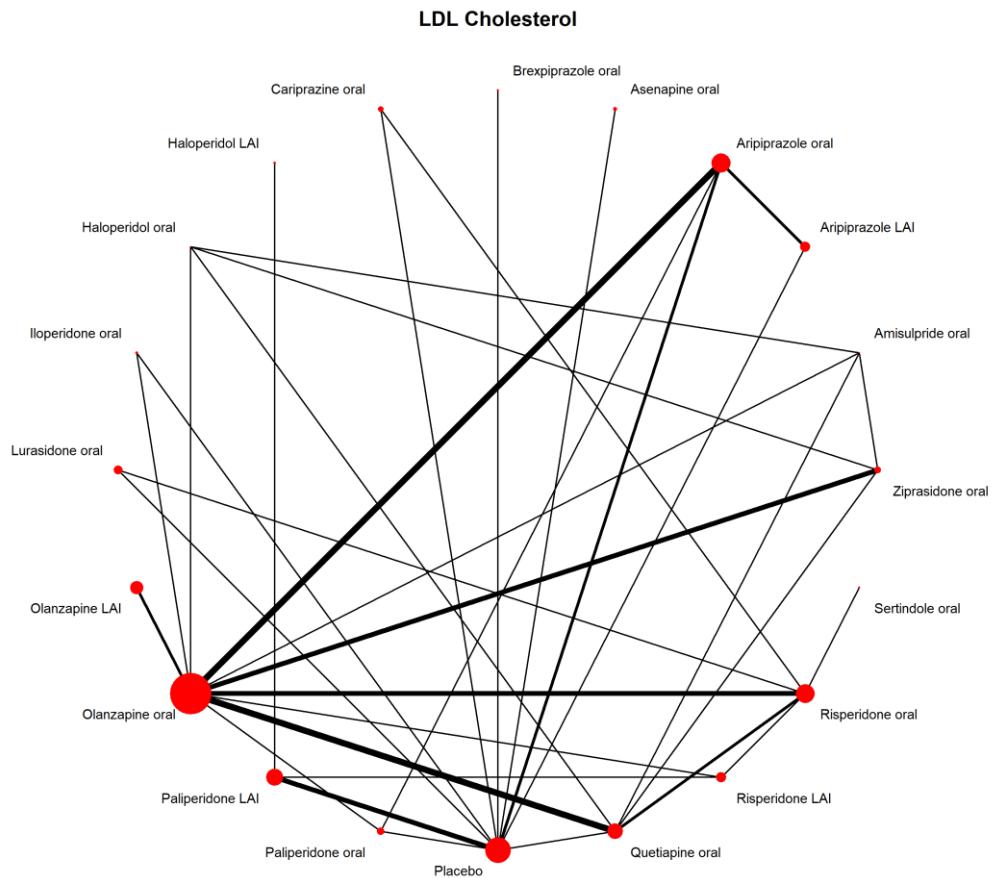

Pairwise meta-analyses are ordered by comparison investigated (in alphabetical order) and a summary effect size is calculated by pairwise meta-analyses of all studies of a specific comparison. The type of effect size measure is mean difference (MD).

Abbreviations: MD=mean difference, 95% CI=95% confidence interval, LAI=long-acting injectable.

7.5 LDL cholesterol

40 studies on 19 antipsychotics with 11954 participants included reported on LDL cholesterol.

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Abbreviations: LAI=long-acting injectable.

Order of treatments is according to SUCRA ranking. Results of the network meta-analysis are presented in the left lower half and results of pairwise meta-analyses in the right upper half. Each cell provides the effect estimate as mean difference (MD) and the corresponding 95% credible interval (95%CrI) of a comparison (left lower half: treatment in column versus treatment in row; right upper half: treatment in row versus treatment in column). Bold print indicates 95% CrI excluding the point of no effect.

Abbreviations: NA=Not available, LAI=long-acting injectable, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

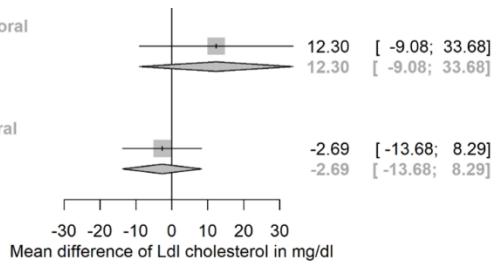

Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

Comparison = Risperidone LAI vs Risperidone oral
 RIS SCH 4178 (n= 45)
 Random effects model
 Heterogeneity: not applicable

Comparison = Risperidone oral vs Sertindole oral
 Thomas 2010_MetabolicSubgroup (n= 189)
 Random effects model
 Heterogeneity: not applicable
 Heterogeneity: $I^2 = 63\%$, $\tau^2 = 19.7618$, $p < 0.01$

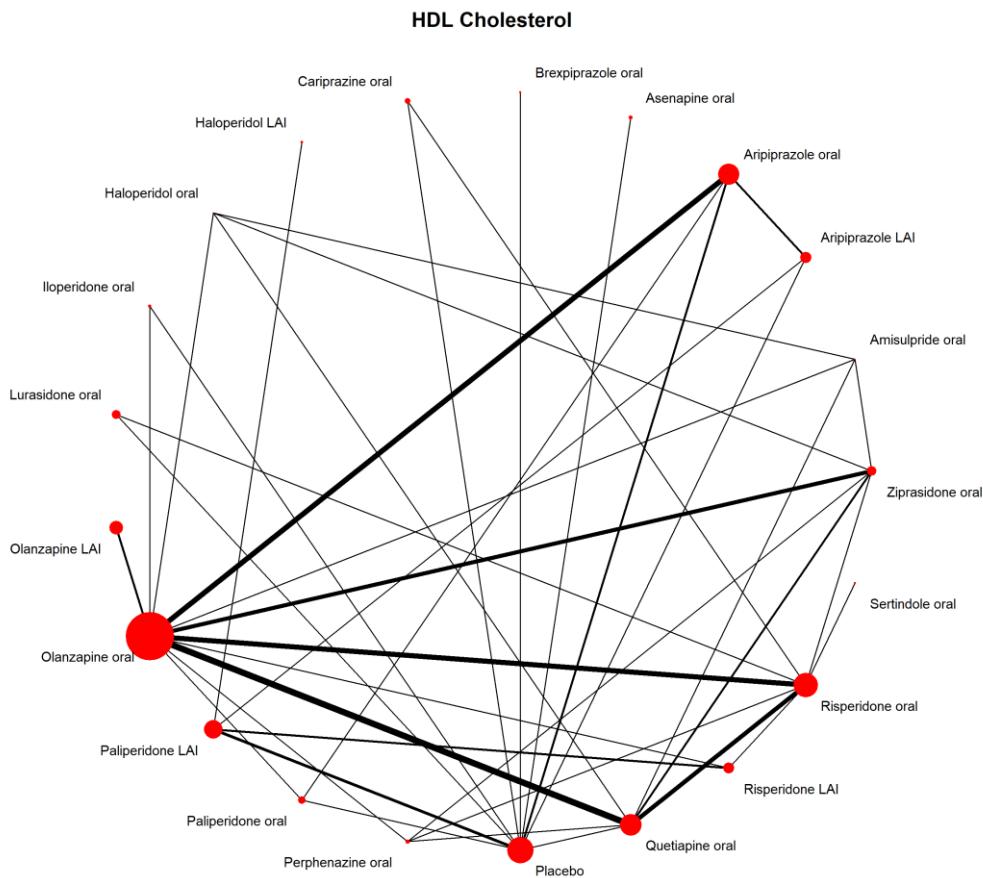

Pairwise meta-analyses are ordered by comparison investigated (in alphabetical order) and a summary effect size is calculated by pairwise meta-analyses of all studies of a specific comparison. The type of effect size measure is mean difference (MD).

Abbreviations: MD=mean difference, 95% CI=95% confidence interval, LAI=long-acting injectable.

7.6 HDL cholesterol

45 studies on 20 antipsychotics with 13736 participants included reported on HDL cholesterol.

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Abbreviations: LAI=long-acting injectable.

Each cell provides the effect estimate as mean difference (MD) and the corresponding 95% credible interval (95%CrI) of a comparison (left lower half: treatment in column versus treatment in row; right upper half: treatment in row versus treatment in column). Bold print indicates 95% CrI excluding the point of no effect.

Abbreviations: NA=Not available, LAI=long-acting injectable, AMI=Amisulpride, ARI=Aripiprazole, ASE=Asenapine, BRE=Brexpiprazole, CAR=Cariprazine, CLO=Clozapine, CPZ=Chlorpromazine, FLP=Fluspirilene, FLU=Fluphenazine, FPX=Flupentixol, HAL=Haloperidol, ILO=Iloperidone, LUR=Lurasidone, OLA=Olanzapine, PAL=Paliperidone, PER=Perphenazine, PIM=Pimozide, PLB=Placebo, QUE=Quetiapine, RIS=Risperidone, SER=Sertindole, THIOR=Thioridazine, TIOT=Tiotixene, TRI=Trifluoperazine, ZIP=Ziprasidone, ZOT=Zotepine.

Forest-plot of results of pairwise meta-analyses (also indicating data of individual studies)

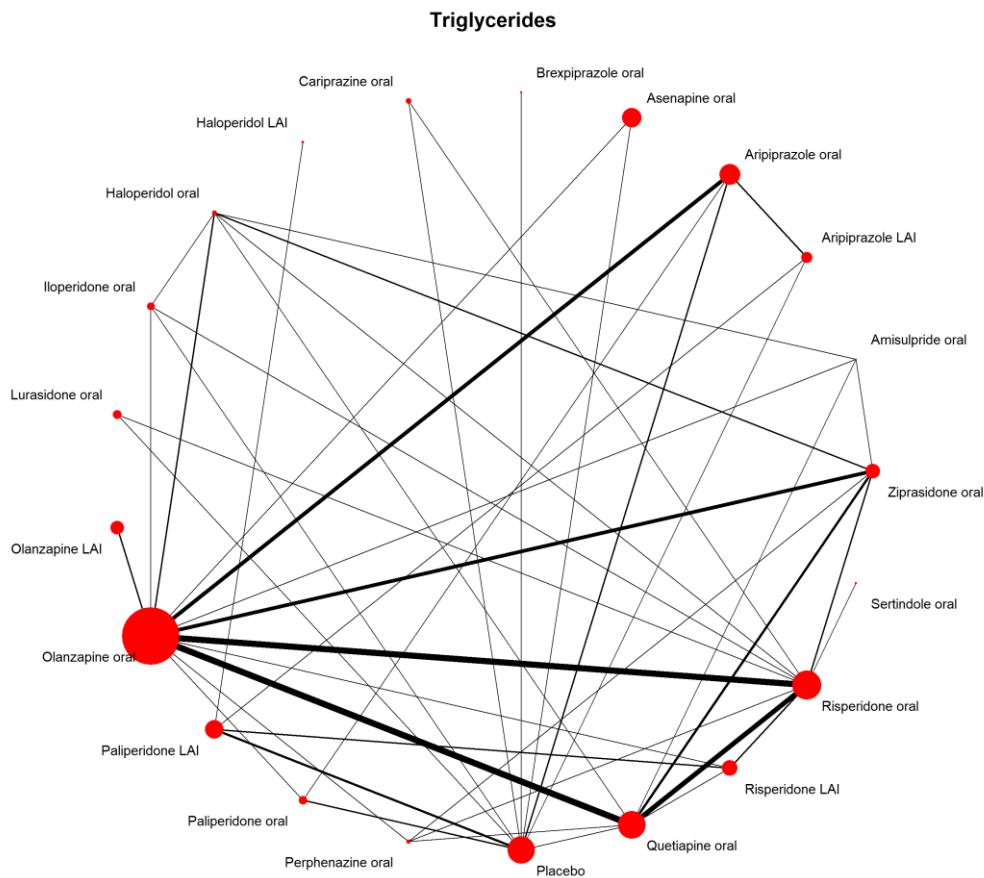

Pairwise meta-analyses are ordered by comparison investigated (in alphabetical order) and a summary effect size is calculated by pairwise meta-analyses of all studies of a specific comparison. The type of effect size measure is mean difference (MD).

Abbreviations: MD=mean difference, 95% CI=95% confidence interval, LAI=long-acting injectable.

7.7 Triglycerides

55 studies on 20 antipsychotics with 17010 participants included reported on triglycerides.

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Abbreviations: LAI=long-acting injectable.

Pimozide	6.16 (-1.78 to 13.74)					
Zotepine	3.87 (2.14 to 5.58)					
Olanzapine	3.82 (3.15 to 4.50)	5.07 (2.44 to 7.98)	12.65 (8.73 to 16.51)	8.09 (4.32 to 11.89)	-2.59 (-3.71 to -1.44)	31.66 (20.32 to 42.84)
Clozapine	4.21 (3.03 to 5.42)	1.64 (-7.08 to 10.26)	15.83 (-2.44 to 32.73)			
Chlorpromazine	5.13 (1.98 to 8.30)	4.94 (-7.93 to 18.90)	13.00 (-2.21 to 29.08)			

Numbers present the MDs with their 95% CrIs from the network-meta-analysis compared to placebo. The order of treatments is according to SUCRA value of the primary outcome weight gain. Colours represent the SUCRA value with more red indicating a higher probability of being the worst drug. Grey cells indicate that no data were available.

Abbreviations: CrI=credible interval, MD=mean difference.

8 Inconsistency in the network meta-analyses of the primary and secondary outcomes

Summary of results:

There was no evidence of inconsistency in direct and indirect estimates for the primary outcome “weight gain”, total cholesterol, LDL cholesterol and HDL cholesterol. Little evidence of inconsistency was observed for number of participants with weight gain, fasting glucose and triglycerides.

Details:

In network meta-analysis, consistency is the agreement between direct and indirect evidence.

We employed global as well as local methods to evaluate consistency.

We investigated consistency locally, i.e. for each comparison that is part of a closed loop, by a SIDE-(Separating Indirect from Direct Evidence)-test ³⁶⁴.

We investigated consistency globally, i.e. of the network as a whole, by a Design-by-treatment interaction test ³⁶⁵.

Outcome	Type of outcome	Model	Number of studies (comparisons) [interventions]	Inconsistent comparisons of detachable comparisons (%) (SIDE-test p <0.10)	p-value of Design-by-treatment test	Judgement
Weight gain	Continuous	Frequentist	110 (57) [29]	5 of 57 (8.8%)	0.471	No evidence of inconsistency
Weight gain	Dichotomous	Frequentist	106 (62) [30]	7 of 62 (11.3%)	0.189	Little evidence of inconsistency
Fasting glucose	Continuous	Frequentist	50 (39) [22]	5 of 39 (12.8%)	0.263	Little evidence of inconsistency
Total cholesterol	Continuous	Frequentist	63 (46) [24]	2 of 46 (4.3%)	0.453	No evidence of inconsistency
LDL cholesterol	Continuous	Frequentist	40 (29) [20]	0 of 29 (0%)	0.443	No evidence of inconsistency
HDL cholesterol	Continuous	Frequentist	45 (35) [21]	3 of 35 (8.6%)	0.654	No evidence of inconsistency
Triglycerides	Continuous	Frequentist	55 (42) [21]	1 of 42 (2.4%)	0.082	Little evidence of inconsistency

It needs to be considered that the statistical power of tests for inconsistency are low when a network is not well connected and/or when there are few/small studies per comparison which is the case for some secondary networks (see network plots).

9 Heterogeneity in the network meta-analysis of the primary outcome “weight gain”

Summary of results:

Estimated across the various treatment comparisons in the NMA, the heterogeneity standard deviation (common- τ) of the Bayesian random effects model was 0.82 kg. No empirical comparators are available to judge heterogeneity for our primary outcome “weight gain” measured as mean difference (MD). Therefore, we additionally calculated effect sizes in standardized mean difference (SMD) in a frequentist setting for which an empirical comparator exist and found low to moderate heterogeneity in comparison with the empirical comparator.

Moreover, we estimated prediction intervals for antipsychotics vs. placebo to assess how much the common heterogeneity affects the relative effect with respect to the extra uncertainty anticipated in a future study. We judged heterogeneity as moderate because the prediction intervals of 15/28 comparisons were different compared to credible intervals in regard to clinically important thresholds followin the CINeMA approach.

Details:

In the table the estimator of between-study-heterogeneity common- τ of the primary outcome is presented. Unfortunately, no empirical comparator is available to judge heterogeneity. As Rhodes et al.³⁶⁶ provided empirical distributions for continuous outcomes only measured as standardized mean difference, we additionally calculated effect sizes in SMD in a frequentist setting and found low to moderate heterogeneity for our primary outcome weight gain.

Outcome	Common- τ of the Bayesian model estimated in NMA	Outcome type used as comparator *	Empirical predictive distribution of τ	Location of the estimated common- τ compared to the quartiles of the empirical predictive distribution	Judgement of heterogeneity
Continuous	Mean	From Rhodes et al. ³⁶⁶	Median (IQR)		
Body weight (MD [kg])	0.82	Outcome estimated as mean difference (MD). No comparator available			
Body weight (SMD)	0.15	Biological marker	0.16 (IQR 0.06, 0.44)	Between 25%- and 50%-quantile	low-moderate

*Intervention comparison type pharmacological vs pharmacological

We present in the following table the results for the primary outcome “weight gain” antipsychotics vs. placebo with prediction intervals. Prediction intervals, which capture heterogeneity, inform about the range of possible effects which could be expected in future studies in different settings. This can be also interpreted as the range of possible effects which could be expected for different patients and is therefore valuable for clinical interpretation³⁶⁷. Additionally, following the CINeMA approach³⁶⁸, we assessed whether the prediction intervals were different compared to credible intervals in regard to the clinically important thresholds (-2/ +2 kg) and the line of no effect (0 kg). We observed that for 14 comparisons prediction intervals in contrast to the credible intervals crossed one threshold (= some concerns) and for one comparison the prediction interval crossed of these clinically important thresholds two (= major concerns). Therefore, overall, we judge the impact of heterogeneity on the interpretation of the primary results as moderate. Please note that the impact of heterogeneity for each possible comparison in the network is included in the CINeMA assessment (see appendix 15).

Drug	Mean difference	Lower limit of 95%-CrI	Higher limit of 95%-CrI	Lower limit of prediction interval	Higher limit of prediction interval	Judgement following CINeMA
Fluspirilene LAI	-9,13	-19,02	1,43	-19,503	1,565	no concerns

10 Results of the network meta-regression analyses of the primary outcome “weight gain”

First we present a summary of the results of the different network meta-regression analyses conducted.

Then we present for each network meta-regression analysis (in this order)

- Network plot (because the network can be different from the primary network because not all studies reported the explored moderator)
- Forest-plot of results of adjusted network meta-analysis (reference intervention placebo)

Summary of results:

In network meta-regression analyses, we investigated the role of several potential effect modifiers (baseline weight, age, gender (percentage women), ethnicity, lifetime exposure to antipsychotics, pharmaceutical sponsorship and study duration). Meta-regression analyses on study level basis could not identify clear moderators of weight gain, because the credibility intervals for the effect (B) were imprecise and/or included the point of no effect except for sponsorship. The MD of any antipsychotic versus placebo was on average 0.45 kg (95% CrI: 0.01 to 0.89 kg) higher in sponsored arms than in non-sponsored study arms. After adjusting for pharmaceutical sponsoring common- τ was reduced from 0.82 to 0.65.

The following table presents the estimated average increase in MD of weight gain (=B) due to the potential moderator in the network meta-regression model and the effects of adjusting for the moderator on the common estimate of heterogeneity (=common- τ).

Analysis	Moderator	B	Credible interval of B	Common- τ (MD)	Credible interval of common tau
NMA	-	-	-	0.82	
NMR	Baseline age (years)	0.02	-0.10, 0.14	0.81	0.58, 1.08
NMR	Gender (proportion women)	-2.05	-7.13, 3.22	0.78	0.54, 1.05
NMR	Ethnicity (black percentage)	0.03	-0.02, 0.08	0.51	0.14, 0.86
NMR	Ethnicity (white percentage)	-0.02	-0.05, 0.01	0.61	0.33, 0.92
NMR	Lifetime exposure to antipsychotics (years)	0.06	-0.11, 0.23	0.78	0.53, 1.09
NMR	Sponsored study arm (yes/no)	0.45	0.01, 0.89	0.65	0.17, 0.99
NMR	Study duration (weeks)	-0.03	-0.07, 0.02	0.84	0.59, 1.12
NMR	Baseline weight (kg)	-0.04	-0.14, 0.06	0.78	0.52, 1.07

Abbreviations: NMA: Network meta-analysis of the primary outcome; NMR: network meta-regression analysis of the primary outcome.

B is the increase in MD that could happen due to the moderator on average according to the network meta-regression model.

The point estimates of B indicate the following moderating effect:

MD of body weight increases on average by 0.02 kg per year of baseline age.

The body weight is on average 2.05 kg more in a study including only women compared to a study including only men.

The body weight is on average 0.03 kg less in a study including only black ethnicity compared to a study including no black ethnicity.

The body weight is on average 0.02 kg more in a study including only white ethnicity compared to a study including no white ethnicity.

MD of body weight increases on average by 0.06 kg per year life time exposure to antipsychotics.

MD of body weight increases on average by 0.45 kg when the study drug is sponsored.

MD of body weight decreases on average by 0.03 kg per week study duration.

MD of body weight decreases on average by 0.04 kg for every kg baseline weight.

Please note that the credible intervals of B for all moderators (except sponsorship) contain the value of no effect (MD=0).

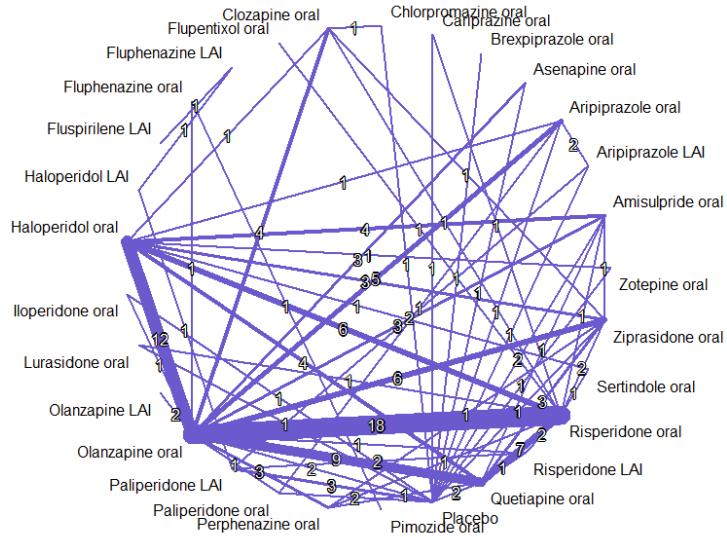

* The common- τ in this NMR is reduced compared to the primary analysis. However, it needs to be noted that information for the specific moderator was only available for a subset of all studies included in the primary analysis. Thus, the common- τ of the adjusted model (NMR) could be compared with the common- τ of the unadjusted models (NMA) in studies with the moderator available. For sponsorship almost no information was missing (only 2 small studies out of 110: Chetvernykh 2008 and Sharma 1991). Therfore, we assumed that common- τ of the unadjusted model NMA after exclusion of these two studies with missing information would not change significantly.

Interpretation:

We identified no clear effect moderator in the network meta-regressions except of potentially sponsorship. Sponsored studies showed 0.45 kg more weight gain compared to non-sponsored studies, but the 95% CrI is rather wide ranging from 0.01 to 0.89 kg. After adjusting for sponsorship common- τ was reduced from 0.82 to 0.65.

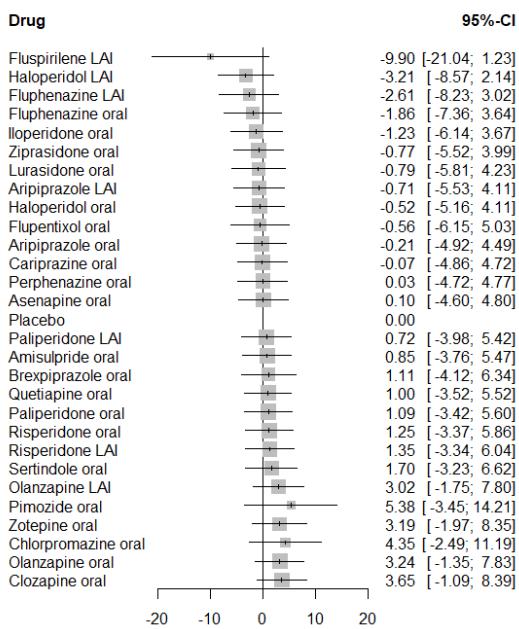

10.1 Baseline age

Network plot

11 Results of the sensitivity analyses of the primary outcome “weight gain”

For each sensitivity analysis we present below (in this order)

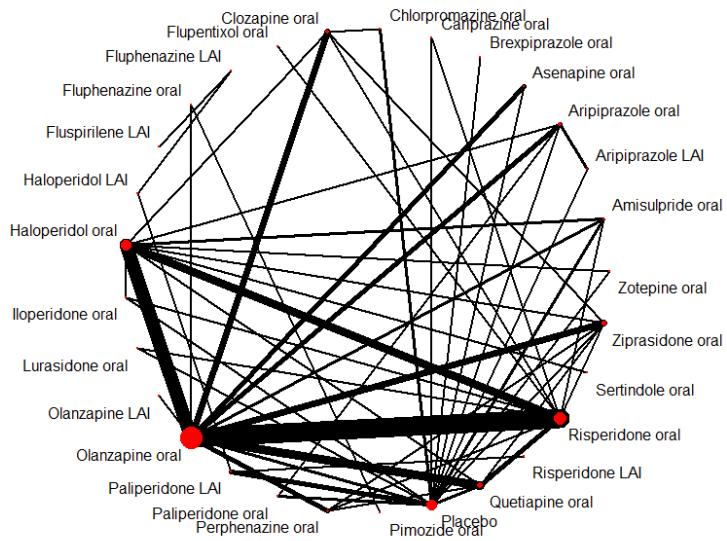

- Network plot
- Results of statistical test for inconsistency of the network and common estimate for heterogeneity
- Forest-plot of results of the network meta-analysis (reference placebo)

Summary of results: In all eight sensitivity analyses, the effect estimates for the primary outcome weight gain and the ranking of antipsychotics remained similar. The observed heterogeneity did not change much. Thus, sensitivity analyses confirmed the primary analysis.

Interestingly, when enriched design studies were excluded, all antipsychotics showed larger MDs (on average +0.63 kg). When only observed cases were considered, more pronounced differences between the antipsychotics were observed.

11.1 Double blind studies only

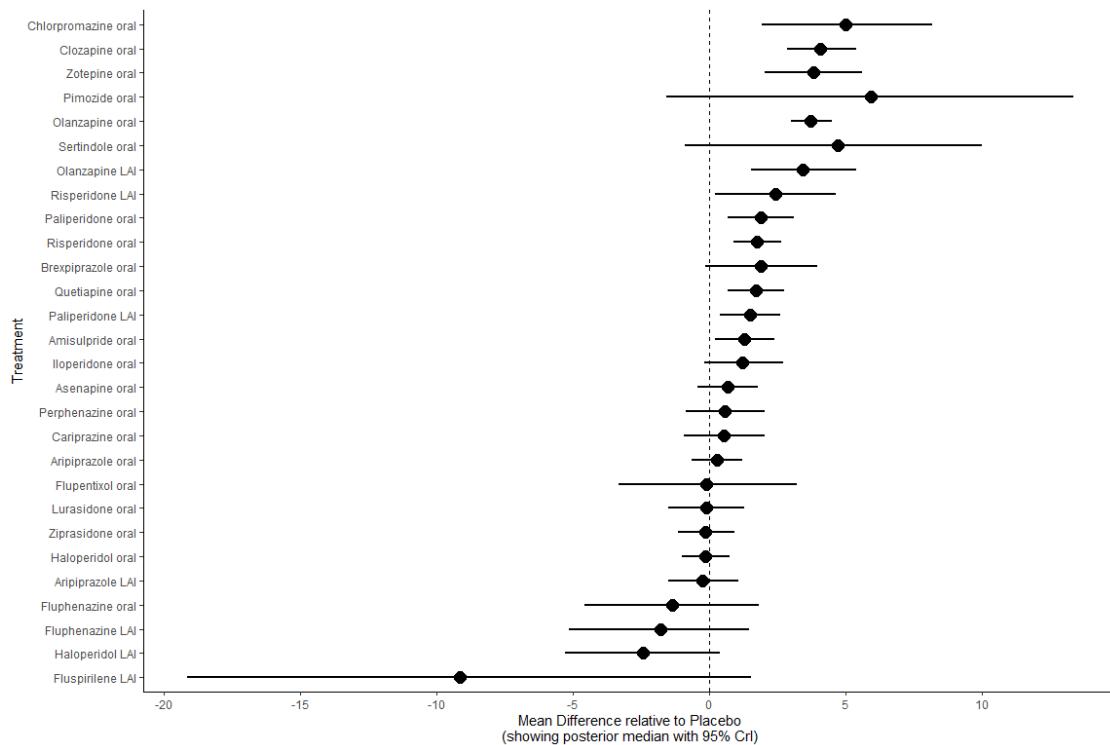

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison)
6 of 45 (13.3%)	0.02	0.804

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

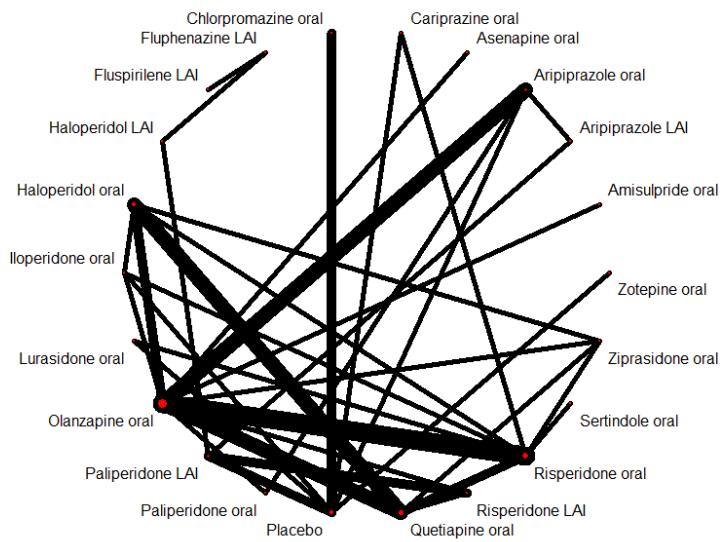

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.2 Analysis of only data of observed cases

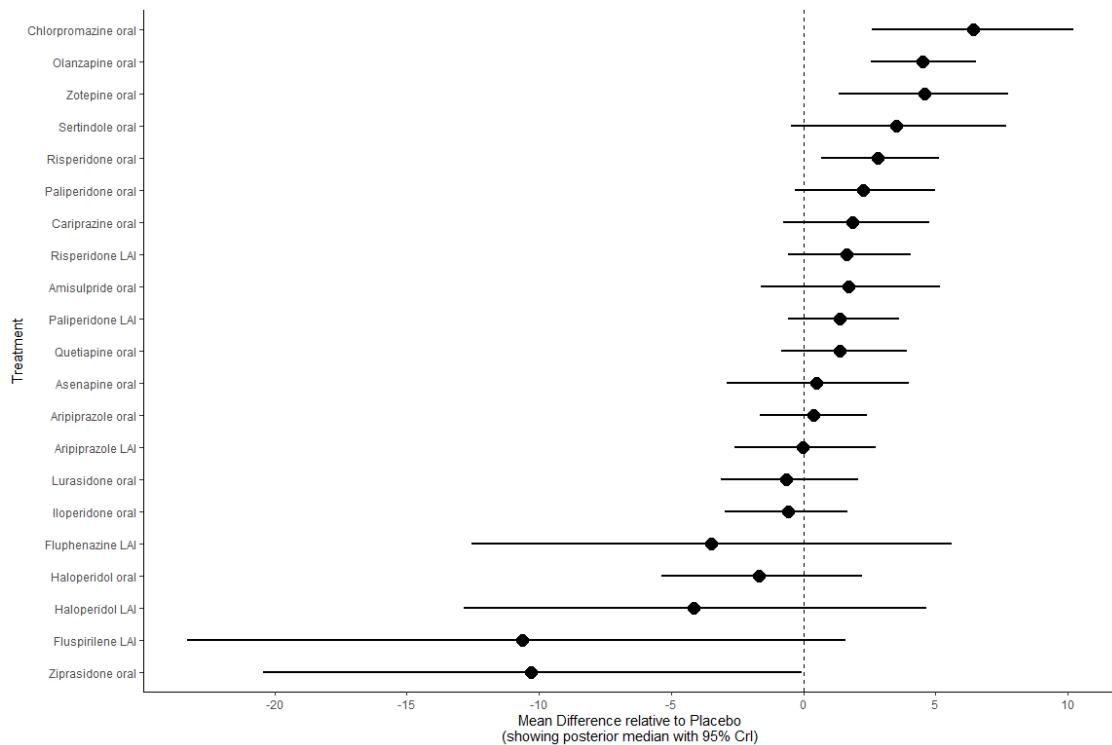

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
1 of 28 (3.6%)	0.656	0.78

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

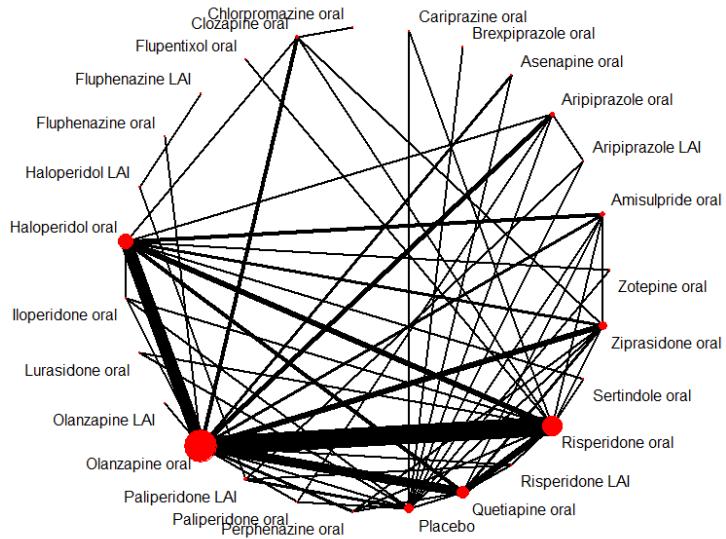

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.3 Exclusion of studies that did not use operationalized criteria to diagnose schizophrenia

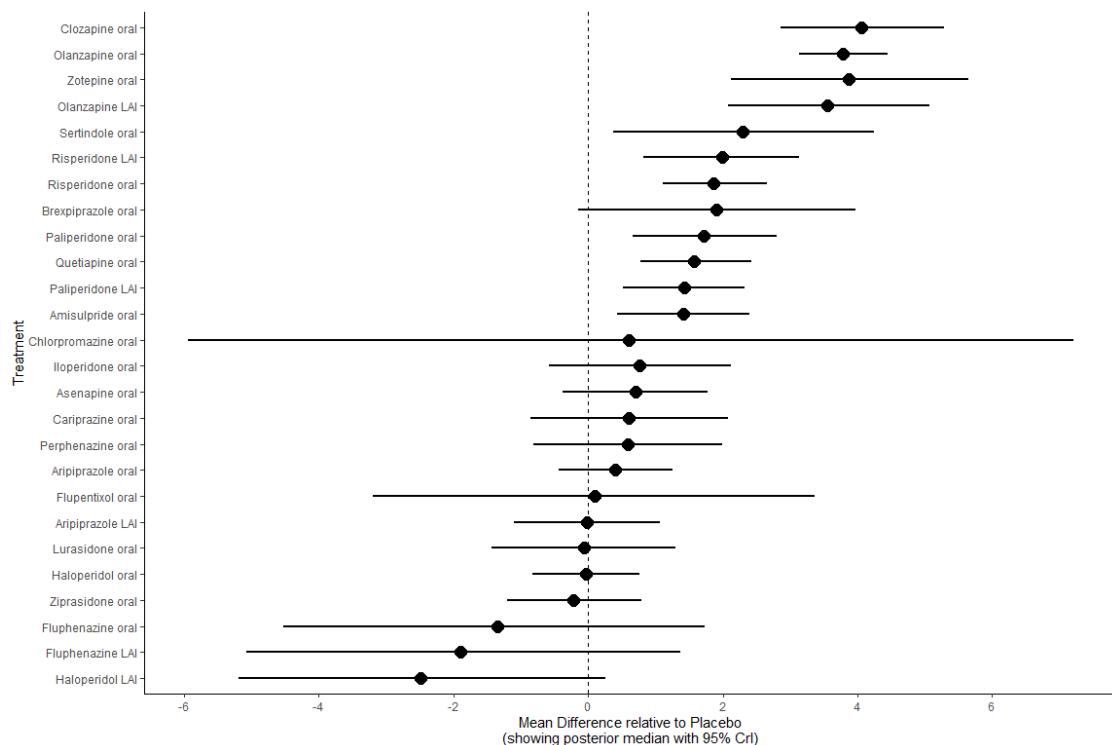

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
5 of 55 (9.1%)	0.508	0.815

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

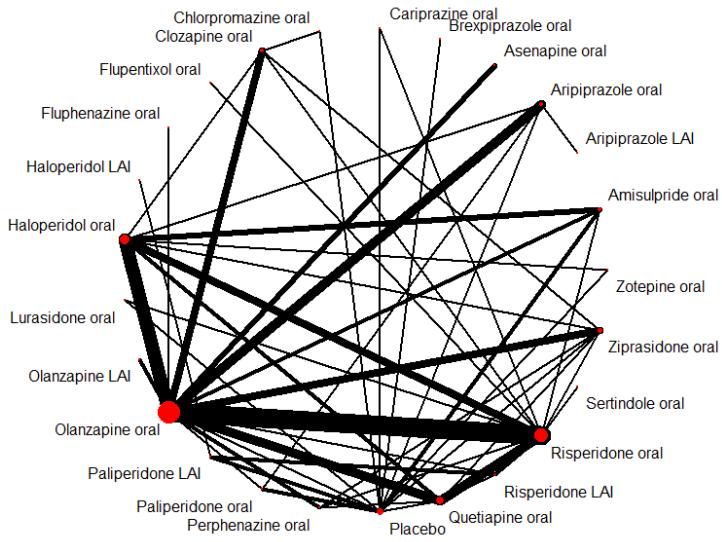

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.4 Exclusion of studies with an overall assessment of high risk of bias

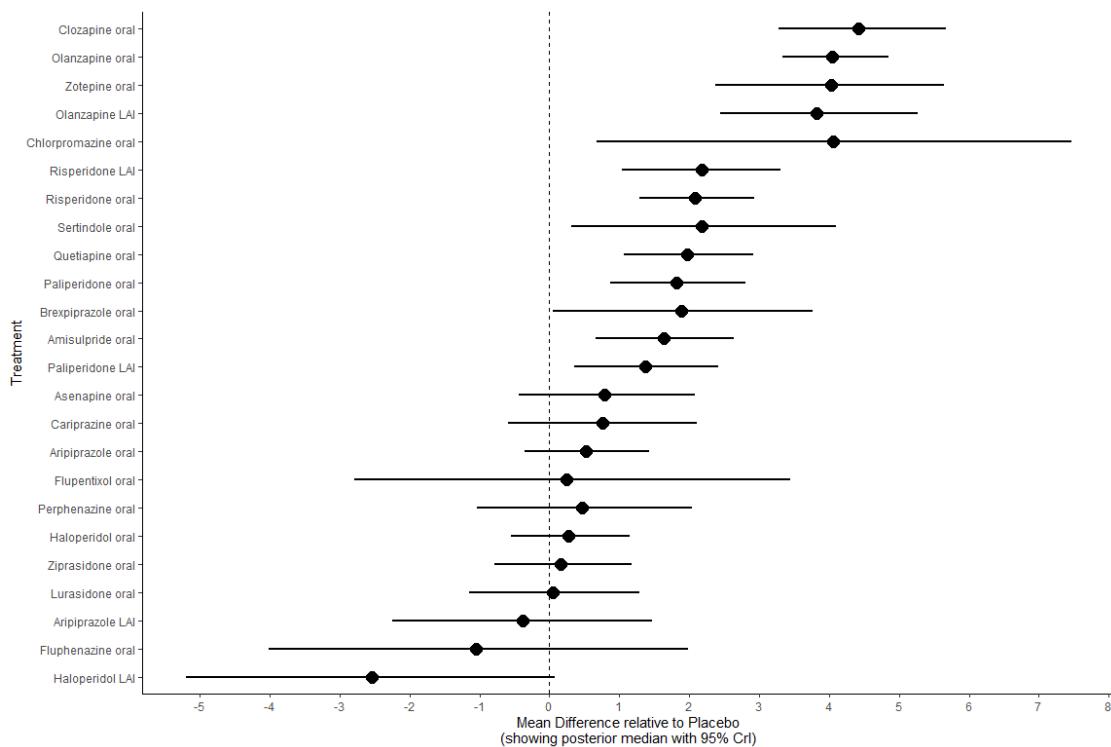

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
5 of 44 (11.4%)	0.005	0.656

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

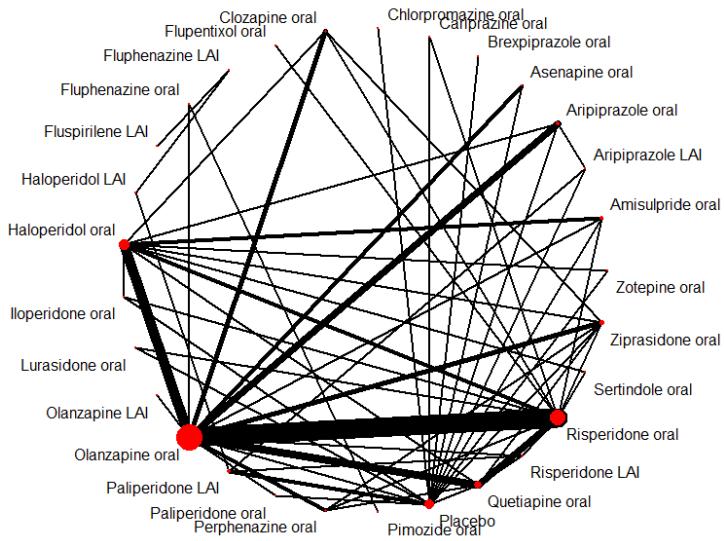

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.5 Exclusion of studies in patients with minimal prior exposure to antipsychotics

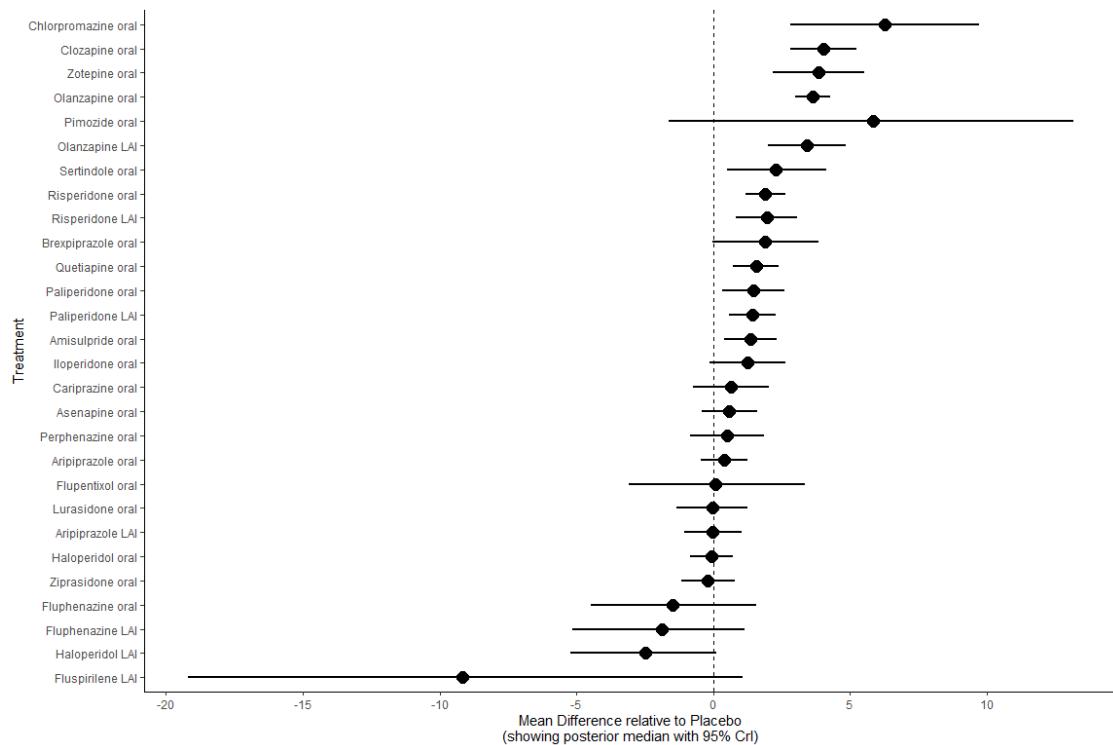

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
6 of 51 (11.8%)	0.003	0.752

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

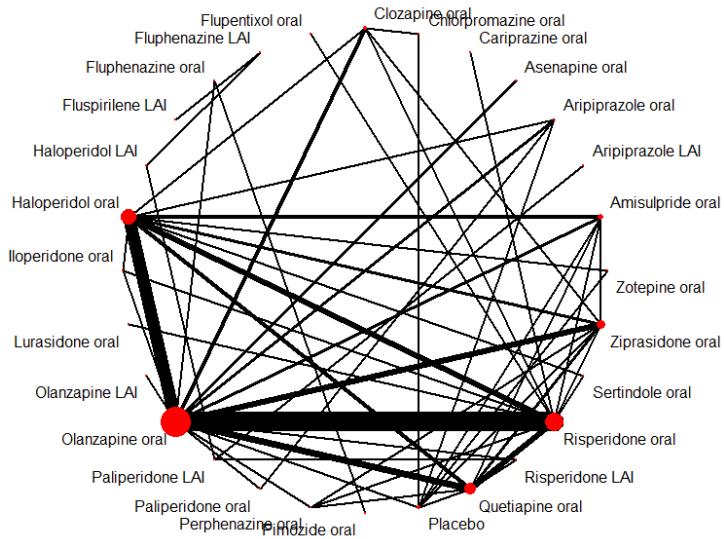

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.6 Exclusion of enriched design studies

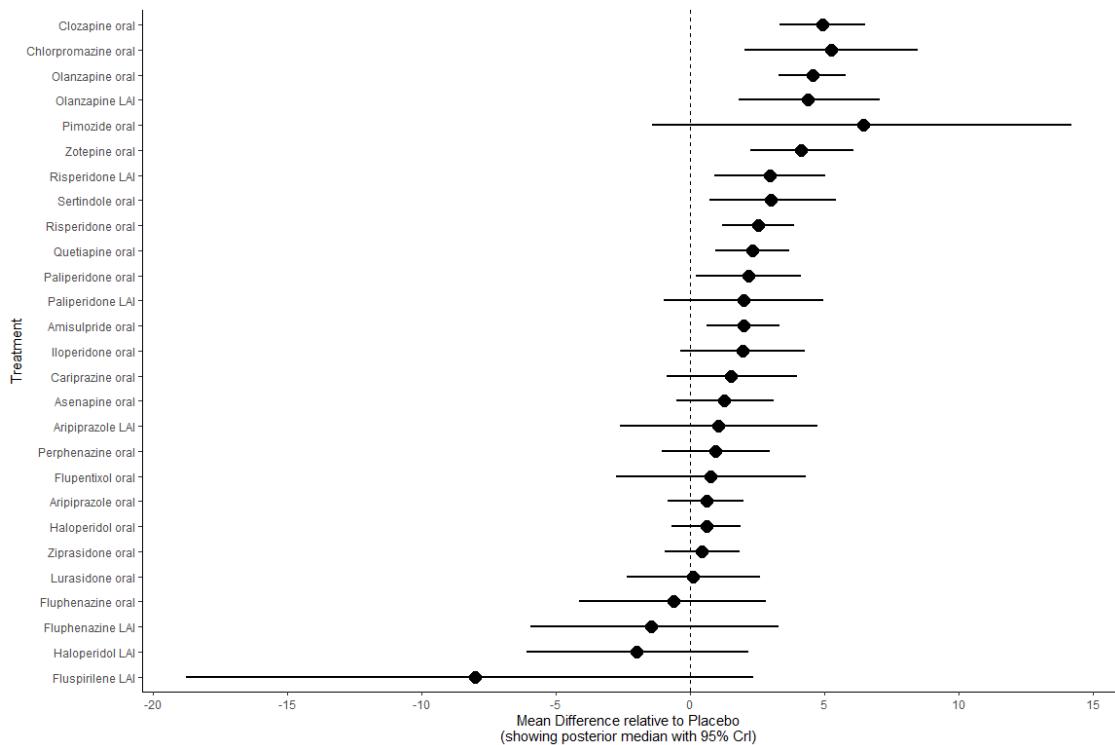

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
5 of 43 (11.6%)	0.807	0.926

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

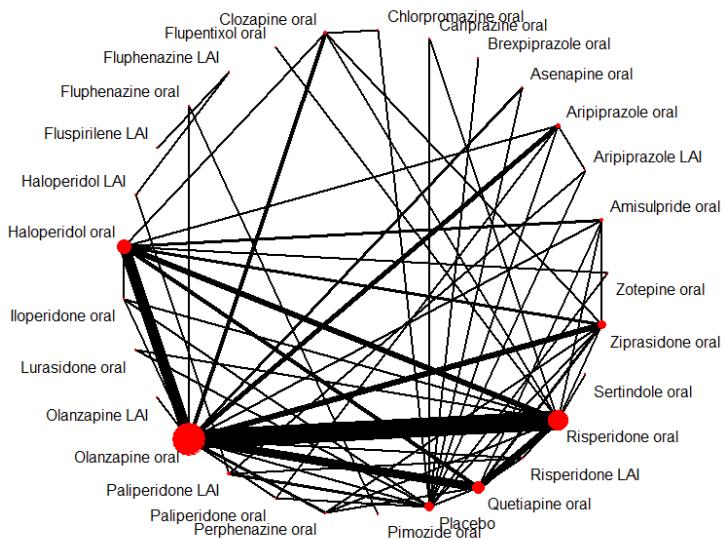

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.7 Exclusion of arms at the lower and upper ends of the range recommended by the International Consensus Study on Antipsychotic Dosing (post-hoc)

In the primary analysis, we included only study arms with doses within the target to maximum range according to the International Consensus Study on Antipsychotic Dosing⁹. Only for special populations such as patients with first episode or primarily negative symptoms for which clinically different dosing regimens are recommended, we included lower doses.

In the following sensitivity analysis, we excluded these studies in special populations using lower doses, specifically, we excluded one study in first episode patients (Kahn 2008), three studies focussing primarily on negative symptoms (Speller 1997, Loo 1997 and Lecrubier 2006). Moreover, we excluded Daniel 1998 which used a dose of Sertindole minimally above the upper end of the International Consensus Study on Antipsychotic Dosing⁹.

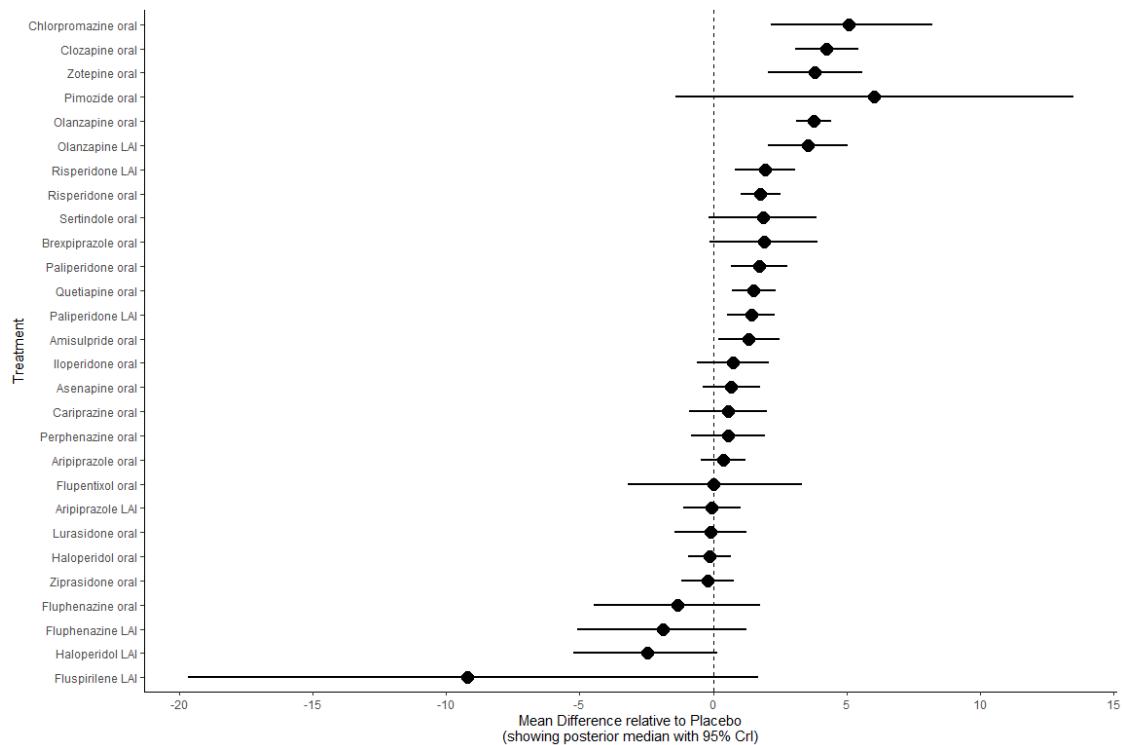

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
5 of 54 (9.3%)	0.442	0.813

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

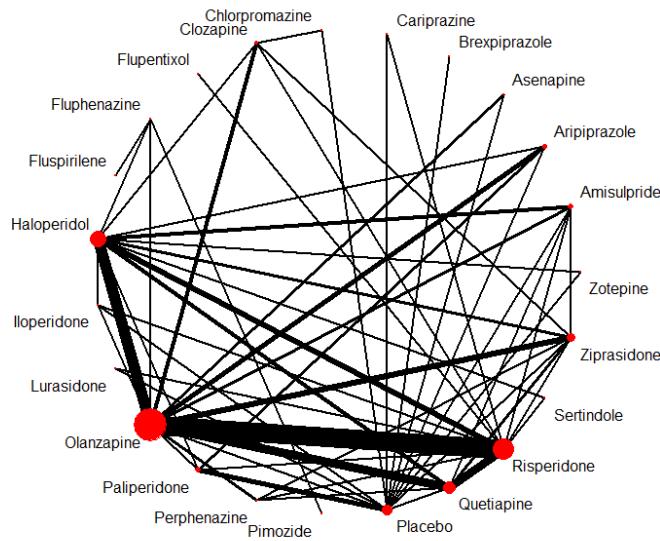

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

11.8 Pooling LAI and oral formulations of the same antipsychotic (post-hoc)

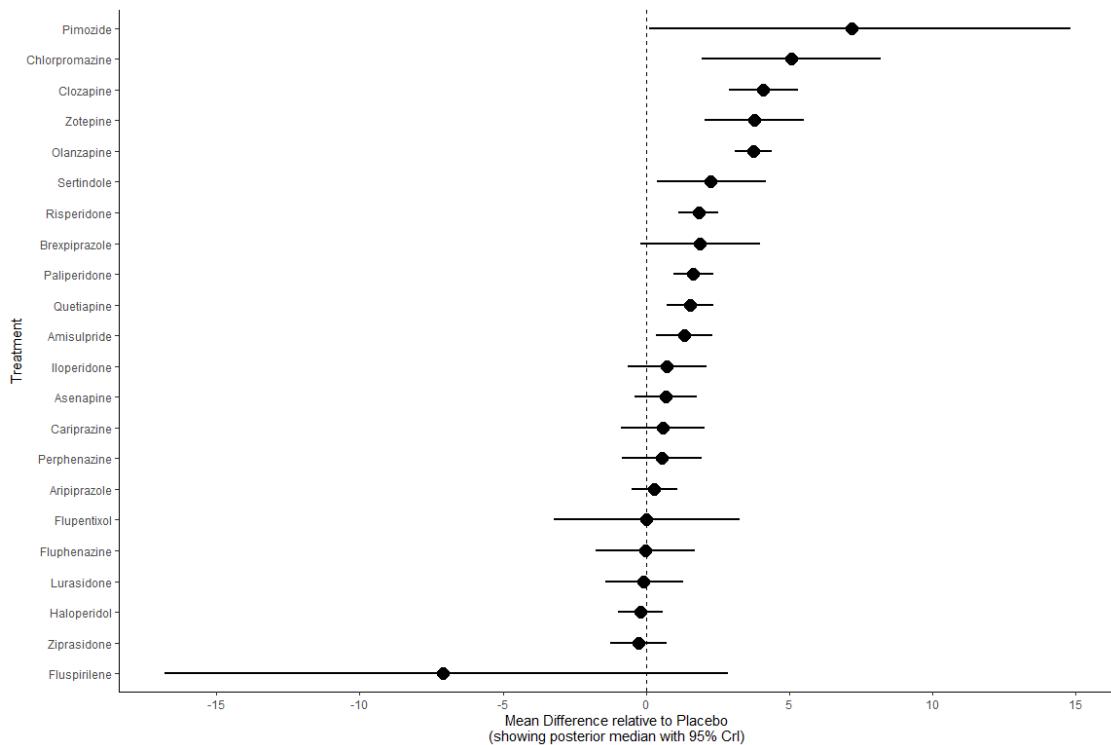

Network plot

Lines link treatments with direct comparisons in trials; thickness of lines corresponds to the number of trials evaluating the comparison; size of the nodes corresponds to the number of participants assigned to the treatment.

Inconsistent comparisons of detachable comparisons (%) (SIDE-test)	P-value of Design-by-treatment test	Common-Tau (standard deviation of differences in effect size between studies of the same comparison) with 95% CrI
6 of 53 (11.3%)	0.339	0.829

Forest-plot of results of network meta-analysis for antipsychotic drugs versus placebo

Network meta-analysis estimates of treatment effect of each drug versus placebo reported as mean difference (MD) in kg. Order of treatments is according to the SUCRA ranking.

Abbreviations: 95% CrI=95% credible interval, LAI=long-acting injectable.

12 Assessment of small-study effect

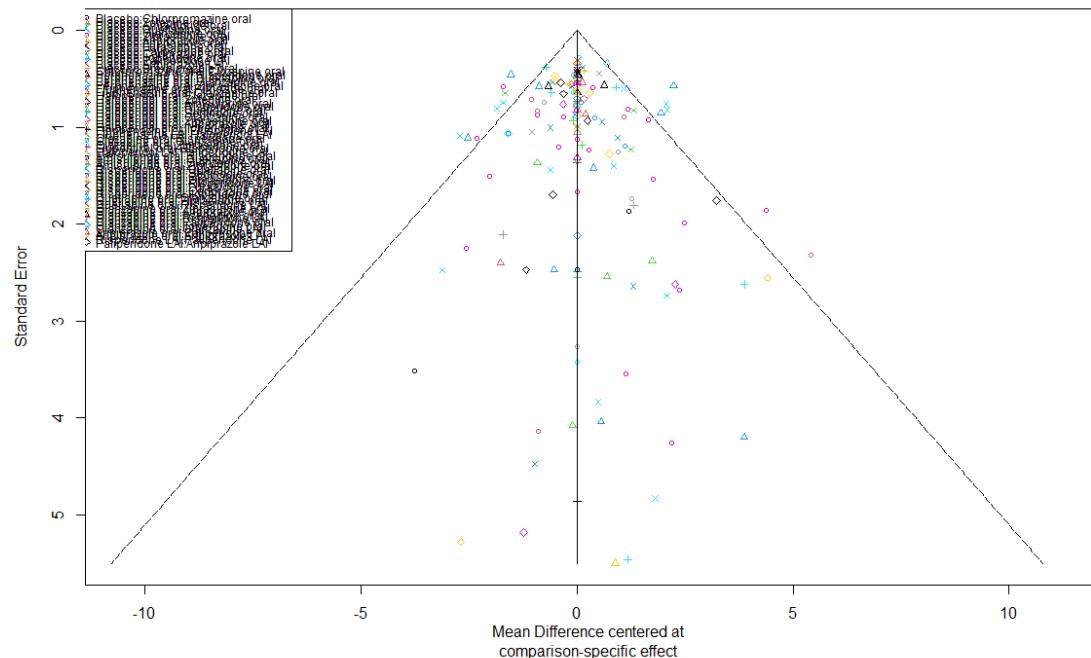

12.1 General notes and findings

We assessed small-study effect (a proxy for publication bias) for the primary outcome “weight gain”. In general, we deem it unlikely that a study was not published because of unfavourable results in secondary outcomes of the original studies. Because the majority of studies assessed weight gain as a secondary safety outcome and only few studies were designed to examine weight gain as primary outcome, the presence of a publication bias is unlikely on a theoretical basis.

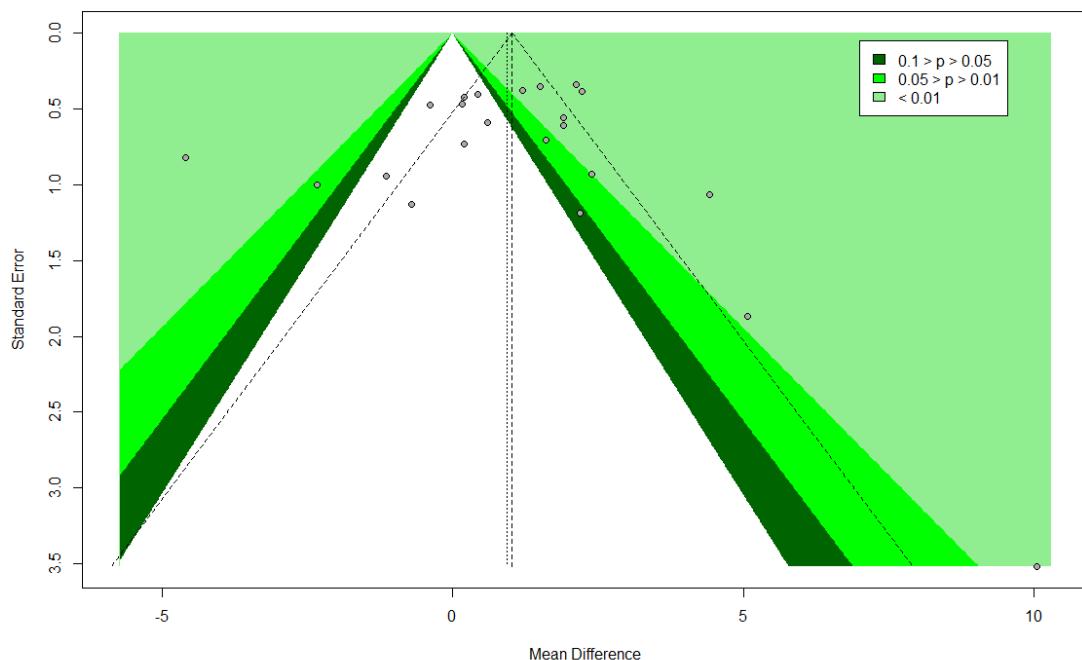

Nevertheless, for our primary outcome “weight gain”, we assessed small-study effects by performing a comparison-adjusted funnel plot, a contour-enhanced funnel plot of all antipsychotics versus placebo and additionally contour-enhanced funnel plots comparing active antipsychotics versus placebo for comparisons with more than 10 studies available.

For our secondary outcomes, we did not assess risk of small-study effect because we deemed the risk for non-publication even lower for fasting glucose and the other lipid parameters compared to our primary outcome “weight gain”.

Comparison-adjusted funnel plot

Contour-enhanced funnel plot of antipsychotics versus placebo

Egger's test for small-study effect

Linear regression test of funnel plot asymmetry
 Test result: $t = -0.31$, $df = 20$, **p-value = 0.7588**

Sample estimates:

bias	se.bias	intercept	se.intercept
-0.4085	1.3125	1.2278	0.2

Details:

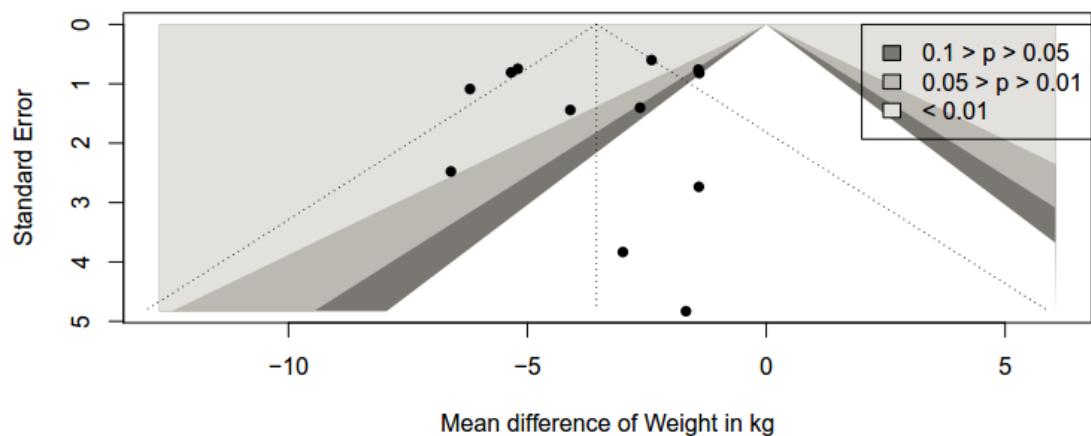

- multiplicative residual heterogeneity variance ($\tau^2 = 6.8836$)
- predictor: standard error
- weight: inverse variance
- reference: Egger et al. (1997), BMJ

Interpretation:

The comparison-adjusted funnel plot showed a symmetrical distribution of studies. In the contour-enhanced funnel plot of all antipsychotics versus placebo there is one small study with a large significant effect but small studies around the pooled effect, small studies with large effects in the opposite direction as well as small studies which found no significant difference between antipsychotics and placebo are missing. This may indicate some small-study effect as a proxy for publication bias. However, as there is only one small-study it is unlikely that small-study bias has an impact on the overall results. Accordingly, the Egger's test indicates no evidence of small-study effect.

12.2 Additional funnel plots for comparisons with more than 10 studies

Contour-enhanced funnel plot for the comparison haloperidol oral vs. olanzapine oral

Egger's test for small-study effect

Linear regression test of funnel plot asymmetry
Test result: $t = -0.37$, $df = 10$, **p-value = 0.7177**

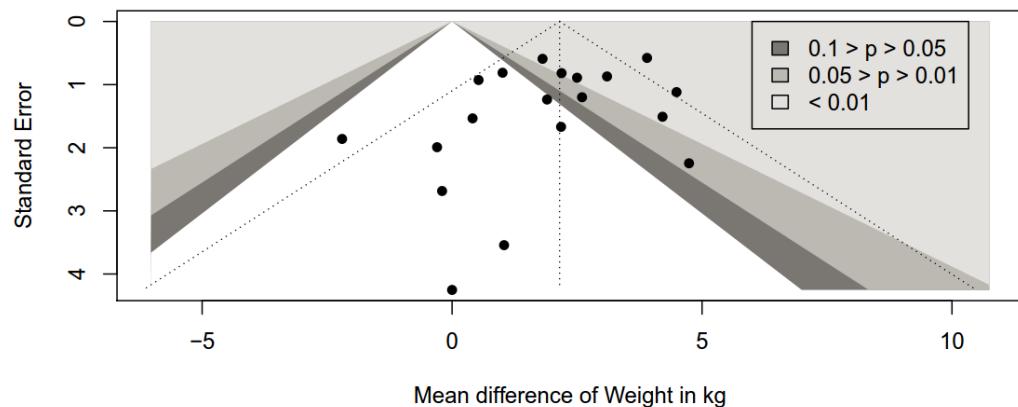

Sample estimates:

bias	se.bias	intercept	se.intercept
-0.4259	1.1449	-2.9762	1.1666

Details:

- multiplicative residual heterogeneity variance ($\tau^2 = 3.6039$)

- weight: inverse variance
- reference: Egger et al. (1997), BMJ

Contour-enhanced funnel plot for the comparison olanzapine oral vs. risperidone oral

Egger test: p -value = 0.22

Egger's test for small-study effect

Linear regression test of funnel plot asymmetry

Test result: $t = -1.28$, $df = 17$, **p-value = 0.2165**

Sample estimates:

bias	se.bias	intercept	se.intercept
-0.8658	0.6745	3.1277	0.7130

Details:

- multiplicative residual heterogeneity variance ($\tau^2 = 1.6716$)
- predictor: standard error
- weight: inverse variance
- reference: Egger et al. (1997), BMJ

Interpretation:

The available small studies are in the white area of no significant difference between the two drugs compared, which are typically those studies which are expected to be unpublished. However, in the specific case of an assessment of a side effect, it may be possible that preferentially non-significant (and not significant results showing a worse outcome with one drug) are published. Thus, the presence of publication bias can not be excluded beforehand. In fact, there was some asymmetry in the funnel plots with small studies missing at one side of the pooled effect. However, there are only few small studies with respect to the overall number of studies so that the pooled effect is not much driven by them.

13 Assessment of risk of bias

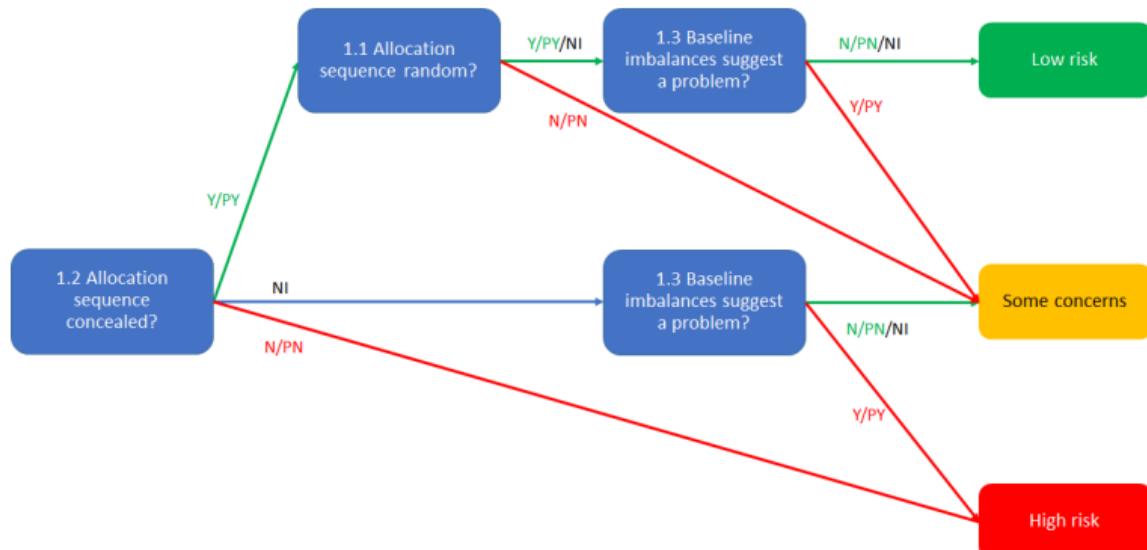

13.1 General notes

For judgement of risk of bias, we followed the concept of the Cochrane Risk of Bias tool 2³⁶⁹. This tool provides a framework for evaluating potential risks of bias in five different domains and provides guidance by signaling questions.

However, it must be noted, that there are not always clear rules and specific situations found in the analysed trials may deviate from the ideal case. Thus, judgement is needed to make decisions and these specific judgements and decisions made by the authors of the review are described below.

13.2 Details of the assessment

Domain 1: RANDOMISATION PROCESS

Algorithm for suggested judgement of risk of bias arising from the randomization process

1.1 Was the allocation sequence random?

In principle, if there was no information about the exact methods (e.g. only stated “randomized”), we stated “not indicated”. For trials investigating second-generation-antipsychotic drugs that were sponsored by pharmaceutical companies, we assume that the sequence generation for randomisation was appropriate, even when it is only stated “randomized”, and we stated “probably yes”. The reason is that we contacted many pharmaceutical companies in the past and all reported use of appropriate methods in these modern studies, even when it was not clearly stated in the primary publications.

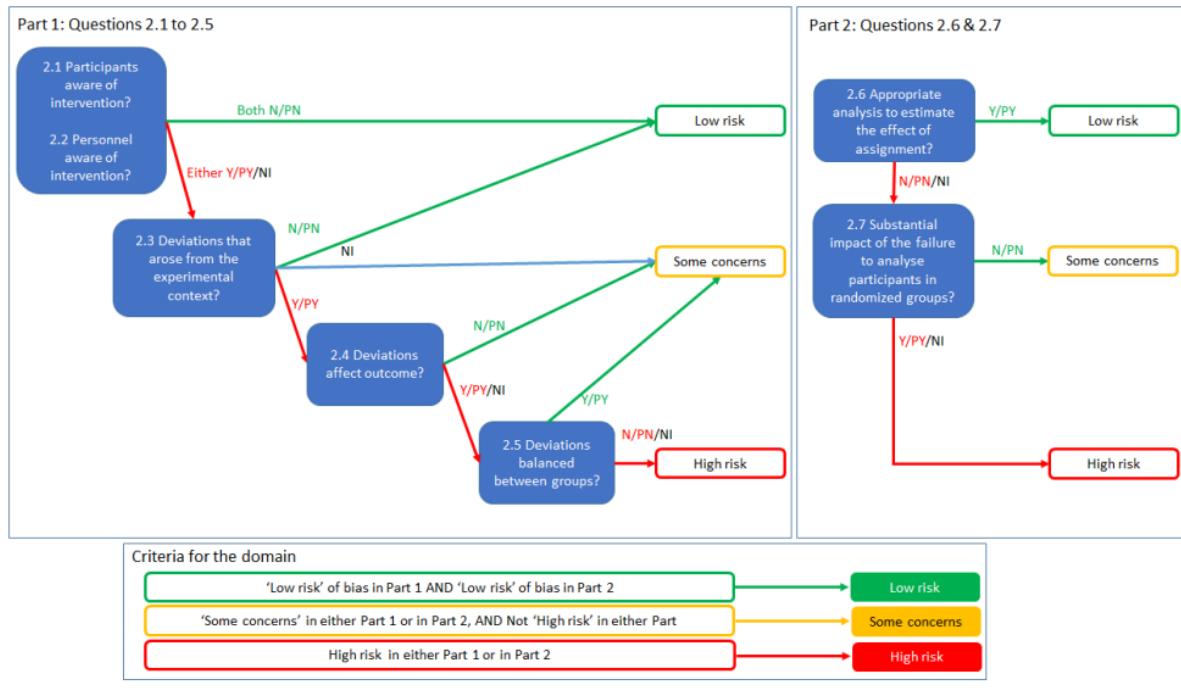

1.2 Was the allocation sequence concealed until participants were enrolled and assigned to interventions?

Similar to 1.1.

1.3 Did baseline differences between intervention groups suggest a problem with the randomisation process?

No specific comments.

Domain 2: DEVIATIONS FROM INTENDED INTERVENTIONS

Part 1:

2.1 Were participants aware of their assigned intervention during the trial?

If only stated “double-blind” without further information about the methods, a judgement is needed. We decided to assume that the method of blinding was appropriate and to state “probably no”, as in studies of antipsychotic drugs blinding can be rather easily achieved by encapsulating drugs with identical capsules.

In placebo-controlled trials, following the suggestion of the RoB2-guidance document³⁶⁹, we assumed unblinding due to side effects. In head-to-head trials of antipsychotics, we did not make this assumption, because the different antipsychotics still have some similarities (overlapping receptor-binding-profiles). Consequently, differences in side-effects are more difficult to evaluate for patients and personal which makes it more difficult to guess the assigned intervention.

2.2 Were carers and people delivering the interventions aware of participants' assigned intervention during the trial?

Similar to 2.1.

2.3 If Y/PY/NI to 2.1 or 2.2: Were there deviations from the intended intervention that arose because of the experimental context?

This question is only relevant for unblinded studies (open, single-blind or placebo-controlled (unblinded due to side effects) trials).

Typically protocol deviations are not reported in detail, which leads to a judgement of “some concerns”. Although protocol deviations due to the experimental context cannot be excluded, we do not deem that substantial protocol deviations (that potentially affect the outcome, see questions below), happen frequently. Thus, we do not expect important bias from deviations of the outcome and a judgement of “some concerns” seems fair or even too punitive.

2.4. Were these deviations likely to have affected the outcome?

No specific comments.

2.5. Were these deviations from intended intervention balanced between groups?

No specific comments.

Part 2:

2.6. Was an appropriate analysis used to estimate the effect of assignment to intervention?

We considered completer analyses as inappropriate because from such analyses patients are excluded post-randomisation due to toxicity or lack of efficacy.

2.7. Was there potential for a substantial impact (on the results) of the failure to analyse participants in the group to which they were randomized?

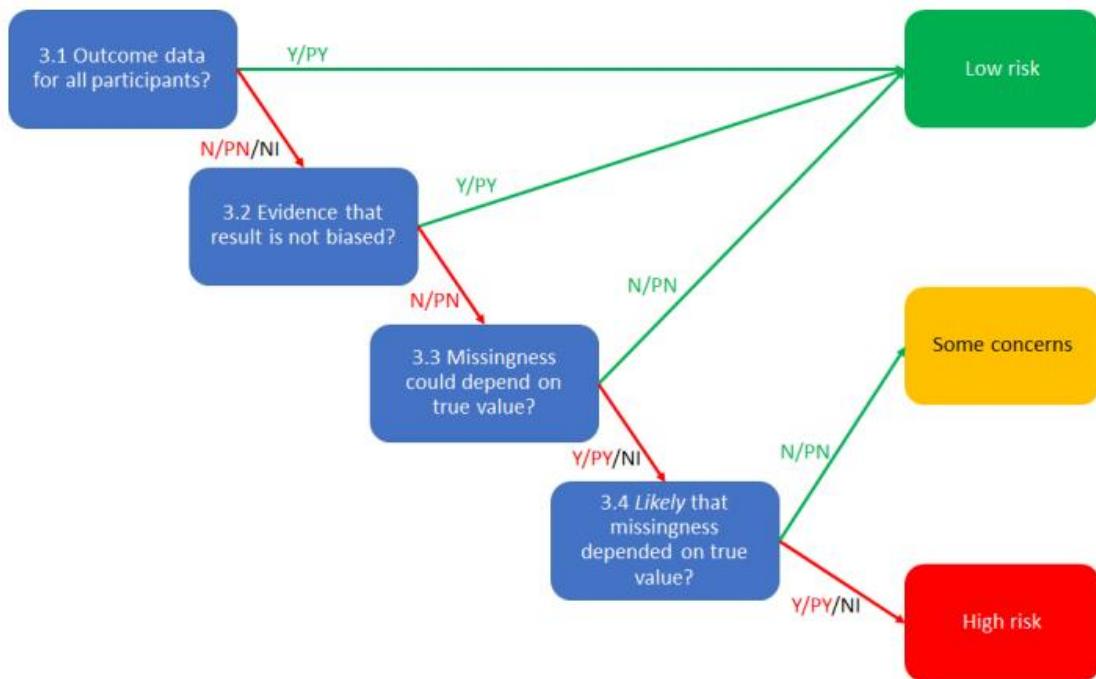

According to the guidance, authors need to make a decision about when exclusion of patients post-randomisation could have a substantial impact on the results.

We considered completer analyses at “some concerns” when the total number of patients with premature study discontinuation was at maximum 20% of the number randomized.

We considered completer analyses at “high risk” when more than 20% of the patients randomized discontinued prematurely.

The decision for this threshold was informed by the work of Xia et al.³⁷⁰.

Domain 3: MISSING OUTCOME DATA

Algorithm for suggested judgement of risk of bias due to missing outcome data

3.1 Were data for this outcome available for all, or nearly all, participants randomized?

For our continuous outcome we used the threshold of 5% (study discontinuation rate at maximum 5% of number of patients randomized) mentioned in the RoB2-guidance-document.

Also, for dichotomous outcomes, we decided for the same threshold of 5%, to rate continuous and dichotomous outcomes similarly.

It must be noted that from the available aggregate data for dichotomous outcomes, it is not possible to know whether a patient who discontinued the study prematurely, already had an event (no missing data) or not (missing data). Thus, there is inevitable uncertainty and the judgement is possibly too punative because data of patients that discontinued prematurely, but had an event before, are infact included in the results.

Moreover, it must be noted that the available aggregate data for continuous outcomes is usually Last-observation-carried-forward (LOCF). Thus some information of patients that discontinued prematurely is included in the results.

3.2 If N/PN/NI to 3.1: Is there evidence that the result was not biased by missing outcome data?

For all outcomes, the available aggregate data is not sufficient to conduct sensitivity analyses: For continuous outcomes, time-point of study discontinuation and characteristics of patients that discontinued are typically not reported. Moreover, the aggregate data typically already include some data of the patients who discontinued prematurely (by LOCF or MMRM) and cannot be used as a basis for a sensitivity analysis (which would mean adding assumed outcomes of patients with premature study discontinuation to the reported result).

Rarely, results were presented by the original investigators using sophisticated methods such as “multiple imputation (MI)” or “mixed-model-of-repeated-measurement (MMRM)” to account for missing outcome data. However, the RoB2-guidance-document recommends to critically consider the underlying assumptions in these analyses. Based on the reported data, this critical assessment of methods is however not possible. Thus we did not consider them appropriate and continued in the decision tree.

3.3 If N/PN to 3.2: Could missingness in the outcome depend on its true value?

If no reasons for study discontinuation are reported, then “probably yes”, because in studies of antipsychotics in schizophrenia, discontinuation due to side effects are likely.

Also for many reported reasons, doubts remain whether the reason is related to side effects.

Moreover, it needs to be noted that in our aggregate data (where events are usually reported from all patients randomized and continuous data is usually reported using LOCF/MMRM) also patients that discontinued due to reasons unrelated to the outcome can affect the result: This is because patients who discontinued prematurely are not at risk for the event anymore and, for continuous data, results of early time points are included in the results.

Thus, all studies with rates of premature study discontinuation above the threshold mentioned in 3.1 need further evaluation.

3.4 If Y/PY/NI to 3.3: Is it likely that missingness in the outcome depended on its true value?

As recommended in the RoB2-guidance-document, we investigated whether there were differences in the total number of participants with premature study discontinuation (dropouts) and in the number of participants with premature study discontinuation for reasons related to the outcome. Thereby, we judged whether it is likely that missingness depended on the outcome and that missingness influenced the outcome substantially (high risk) or to some extent (some concerns).

For the outcomes, we judged the mechanism of missingness and its potential impact on the result according to the following algorithm:

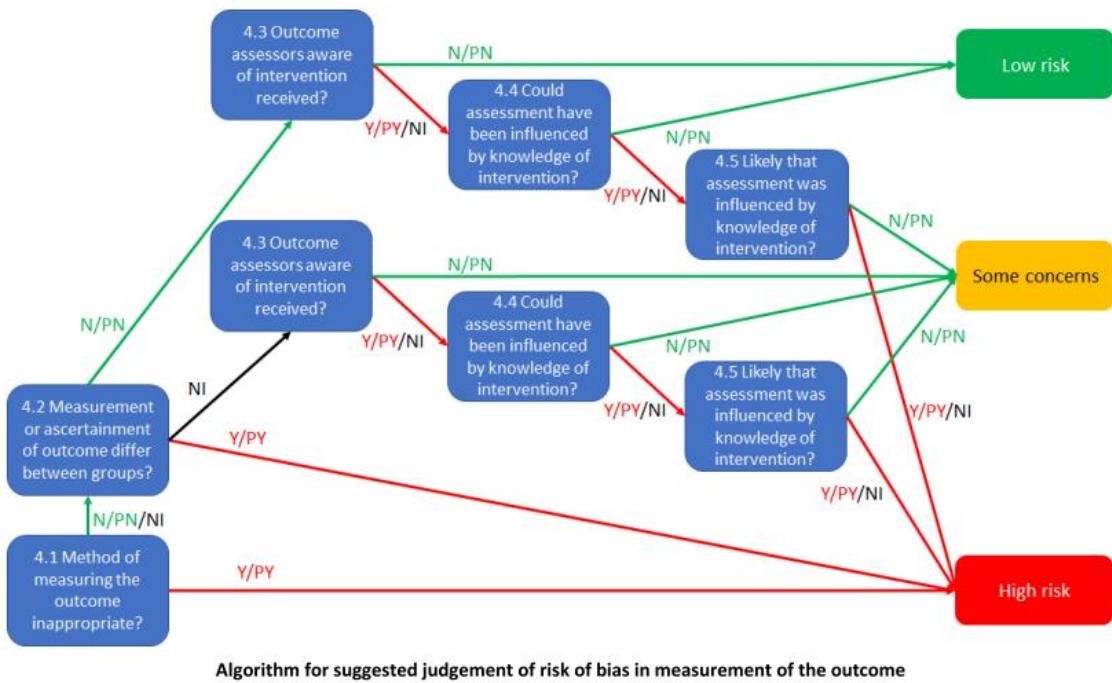

When the rate of study discontinuation for any reason was $\leq 20\%$, we judged at some concerns. This threshold was informed by the work of Sackett et al.³⁷¹ and Xia et al.³⁷⁰. Otherwise proceed.

When the rate ratio of study discontinuation for any reason (between two groups compared in a trial) is $<0.5/ >2$ (half/double), we judged at high risk. Otherwise proceed.

When the rate of study discontinuation due to related reasons (i.e. due to metabolic side effects) was $\leq 20\%$, we judged at some concerns. Otherwise proceed.

When the rate of study discontinuation due to related reasons (between two groups compared in a trial) is $<0.5/ >2$ (half/double), we judged at high risk of bias, when $\geq 0.5/ \leq 2$, we judge at some concerns.

Domain 4: MEASUREMENT OF THE OUTCOME

4.1. Was the method of measuring the outcome inappropriate?

No specific comments.

4.2. Could measurement or ascertainment of the outcome have differed between intervention groups?

No specific comments.

4.3. Were outcome assessors aware of the intervention received by study participants?

In head-to-head studies of antipsychotic drugs, when only reported that the study was double-blind, we assumed that blinding was appropriate and stated “probably no” (similar to 2.1.).

In open trials or double-blind placebo-controlled trials (with potential unblinding of study personal, see 2.1.) we checked if there were particular methods to blind the outcome assessors. If such particular methods were not explicitly described, we assumed that the outcomes were assessed by study personal and answered “probably yes”.

For all outcomes, we considered the personal/external raters (and not the patient him- or herself) to be most important for the outcome assessment (observer-reported outcome; modern single-blind studies in the field of schizophrenia have particularly blinded raters, e.g. with remote-ratings, which emphasizes the role of the rater as outcome assessor).

4.4 If Y/PY/NI to 4.3: Could assessment of the outcome have been influenced by knowledge of intervention received?

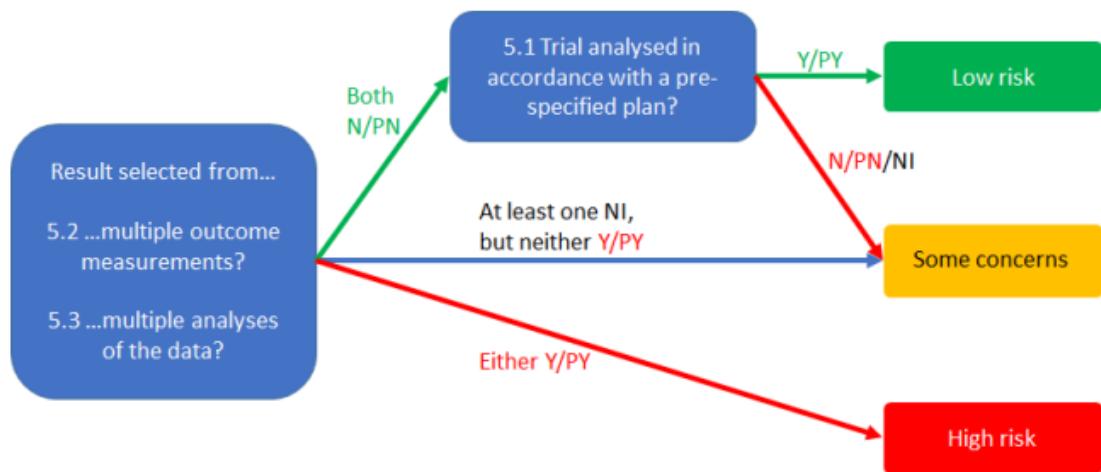

We judged the continuous tolerability outcomes (change in weight gain, parameters of the lipid and glucose metabolism) as not influenced by the knowledge of the intervention, because these are measured by independent objective measuring devices. If the dichotomous outcome number of participants with weight gain was assessed by using objective thresholds like 7% weight gain, we assumed that the assessment was not influenced by knowledge of the intervention and answered “no”. If it was only stated that dichotomous weight gain was “significant” without further details, we assumed that objective criteria were underlying and stated “probably no”.

Was dichotomous weight gain reported only as adverse event without further details we assumed that knowledge of the intervention could possibly have had an influence on the judgement and answered “not indicated”.

4.5 If Y/PY/NI to 4.4: Is it likely that assessment of the outcome was influenced by knowledge of intervention received?

In general we considered the influence of knowledge of intervention received as minor, resulting in a judgement of some concerns.

Domain 5: SELECTION OF THE REPORTED RESULTS

Algorithm for suggested judgement of risk of bias in selection of the reported result

5.1. Were the data that produced this result analysed in accordance with a pre-specified analysis plan that was finalized before unblinded outcome data were available for analysis?

Typically the analysis plan was not available. In this case, we followed the recommendations of the Cochrane handbook¹⁰ and compared the reported results with the reported methods section and with the outcomes that are expected for such trials as informed by other trials.

Is the numerical result being assessed likely to have been selected, on the basis of the results, from...

5.2. ... multiple eligible outcome measurements (e.g. scales, definitions, time points) within the outcome domain?

No specific comments.

5.3 ... multiple eligible analyses of the data?

No specific comments.

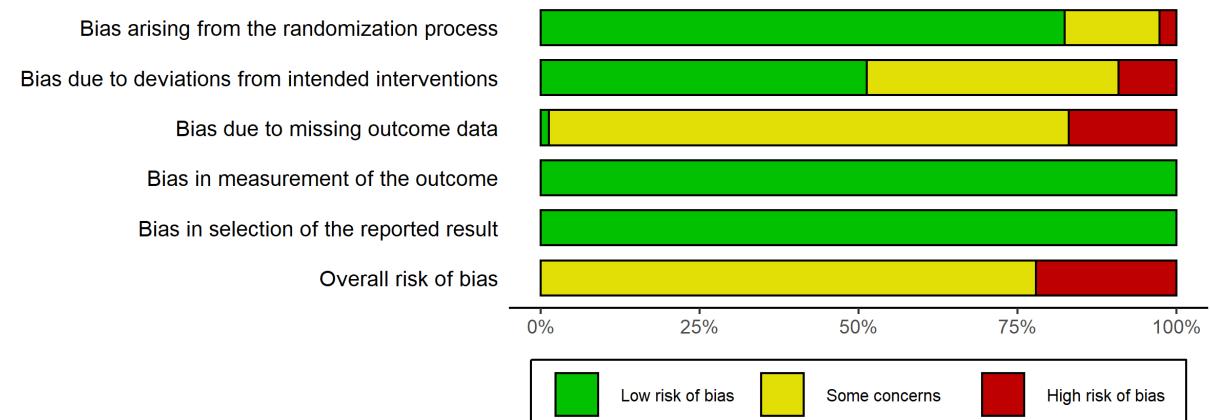

Overall risk of bias:

Overall risk-of-bias judgement	Criteria
Low risk of bias	The study is judged to be at low risk of bias for all domains for this result.
Some concerns	The study is judged to raise some concerns in at least one domain for this result, but not to be at high risk of bias for any domain.
High risk of bias	The study is judged to be at high risk of bias in at least one domain for this result. Or The study is judged to have some concerns for multiple domains in a way that substantially lowers confidence in the result.

We judged a study at overall high risk of bias when 4 or more domains were rated as “some concerns”.

13.3 Judgement per outcome (overall and per study)

13.3.1 Primary outcome “weight gain”

14 Assessment of confidence in estimates

14.1 General notes

We used the official webtool at <https://cinema.ispm.unibe.ch/> and followed the CINeMA-guidance-document³⁶⁸.

The CINeMA-tool provides a framework for evaluating the confidence in the estimates of a network meta-analysis in six different domains. It uses the original data to run a network meta-analysis in order to evaluate the results for each comparison and to calculate a contribution matrix. Therefore, some settings and judgements need to be given, which we report in the following:

We evaluated confidence in estimates of network meta-analysis for the primary outcome “weight gain”.

We chose random-effects models for network meta-analysis similar to the models used in our analyses. The default method is an inverse-variance meta-analysis.

The results of the CINeMA assessment for each comparison are given as a colour code in the league table for the primary outcome.

14.2 Details of the assessment for the primary outcome “weight gain”

Domain 1: WITHIN-STUDY-BIAS

We used the overall risk of bias rating from the Cochrane risk of bias tool 2 (see above).

For studies with multiple comparisons, we used the worst overall risk of bias rating of all comparisons as the overall risk of bias rating of the study (i.e. when one comparison was judged at high risk, then the whole study was considered as at high risk).

Domain 2: REPORTING BIAS

For this domain, suppression of negative findings (publication bias) and omission of unfavourable results from study reports (outcome reporting bias) needs to be considered (time-lag-bias is improbable as antipsychotic drugs are not very recently developed drugs).

For the judgement concerning a potential publication bias of the primary outcome “weight gain”, we considered the funnel plots and the Egger-test reported above which did not yield strong indication for the presence of small-study effect (a proxy for publication bias). Moreover, in general, we deemed it unlikely that studies are not published at all for unfavourable secondary outcomes and weight is mostly reported as such in studies of schizophrenia. Only few modern studies are designed to examine weight gain and metabolic parameters. Therefore we deemed the risk for publication bias low.

For the judgement of a potential outcome reporting bias, we considered the recommendations of the Cochrane handbook¹⁰ and the ORBIT-framework³⁷². We included in the assessment also studies that reported no usable data for any of the outcomes. We expected every study to report data on continuous weight gain as it is one of the most important side effects. The measurement of weight can be easily performed, is available everywhere and not associated with substantial costs. Even if not systematically recorded and analyzed, as it could be the case especially in older trials, probably in most of the studies weight was monitored. Therefore, we assumed all studies which did not report continuous weight gain as potentially suspicious for outcome reporting bias irrespective of their primary outcome.

We judged all comparisons for which direct evidence was available (i.e. the comparison was examined in at least one original trial) as potentially affected (high risk) by outcome reporting bias when the number of participants for which continuous weight data was not reported was above 20% of all participants across all studies for the specific comparison. Conversely, we judged all comparisons at low risk for outcome reporting bias when for at least 80% of the participants weight gain was reported across studies. For comparisons for which only indirect evidence was available it is difficult to assess the risk of outcome reporting bias (because the estimate is derived from multiple

other comparisons in the network which can be at high or low risk) and we assumed some concerns in the domain of reporting bias.

Domain 3: INDIRECTNESS

Population: We included all studies with participants diagnosed with schizophrenia or related disorders (such as schizophreniform or schizoaffective disorders) without further restrictions, because we assumed the occurrence of metabolic side effects not affected by the stage of the disease and comparable in special populations (e.g. participants with predominant negative symptoms).

Interventions: All investigated interventions were licenced antipsychotic drugs (or placebo) and thus directly relevant for the research question.

Outcomes: The selection of outcomes compromises the most important metabolic parameters and is thus directly relevant for the research question.

Setting: We included studies conducted with out-patients, in-patients or both.

Domain 4: IMPRECISION/ Domain 5: HETEROGENEITY/ Domain 6: INCOHERENCE

These three domains require to set thresholds for clinically important differences between interventions.

For our primary outcome “weight gain” we considered a difference outside the interval -2 kg to +2 kg clinically important.

Summarizing judgements across the six domains: OVERALL CINeMA LEVEL

In the CINeMA framework, the overall levels of confidence in the estimates are:

1. high
2. moderate
3. low
4. very low

The CINeMA-guidance-document³⁶⁸ suggests for each comparison to start at the first level (i.e. high) and to downgrade for one level for a rating of “some concerns”, and by two levels for a rating of “major concerns”. In case, several domains are rated at some concerns or major concerns, it is recommended to consider judgements on different domains jointly rather than in isolation. The reason is that domains are interconnected and downgrading more than once for related concerns should be avoided. (The following examples are given in the guidance document: Heterogeneity will increase imprecision in treatment effects and may be related to variability in within-study bias or the presence of reporting bias. Indirectness includes considerations on intransitivity, which manifests itself in the data as statistical incoherence. In the worked example there is ‘some concerns’ for imprecision and heterogeneity and ‘major concerns’ for incoherence. Downgrading by two levels is considered to be sufficient in this situation, because imprecision, heterogeneity, and incoherence are interconnected.)

Based on these recommendations, we used the following approach to reach an overall level of confidence for each comparison and outcome:

- 1 judgement of “some concerns” leads to downgrading by 1 level.
- 1 judgement of “major concerns” leads to downgrading by 2 levels.
- 2 judgements of “some concerns” could be interconnected and do not justify downgrading more than by 1 level.
- 1 judgement of “major concerns” and up to 2 judgements of “some concerns” or 1 additional judgement of “major concerns” could be interconnected and do not justify downgrading by more than 2 levels.

2 judgements of “major concerns” and any additional judgements of “some concerns” or “major concerns” (or more than 4 judgements of some concerns) lead to downgrading by three levels (the maximum).

To rate the 65 direct and 341 indirect comparisons we used the generic approach described above.

15 Heterogeneity in the network meta-analyses of the secondary outcomes

Summary of results:

Heterogeneity was low for the dichotomous outcome number of participants with weight gain. When calculated in standardized mean difference (SMD) and compared to the empirical comparator of Rhodes et al.³⁶⁶ we found low heterogeneity for LDL cholesterol and HDL cholesterol. For fasting glucose, total cholesterol and triglycerides heterogeneity ranged from low to moderate.

Details:

For the dichotomous outcome number of participants with weight gain we compared the estimator of between-study-heterogeneity τ with empirical distributions for τ provided by Turner et al.³⁷³.

For the other continuous outcomes measured as mean differences we added calculations in SMD to can compare them to Rhodes et al.³⁶⁶.

We judged heterogeneity as low when common- τ was below the 25% quantile, as low-moderate when between 25% and 50% quantile, as moderate-high when between 50% and 75% and as high when above the 75% quantile.

Below, we present the heterogeneity observed in the network meta-analyses of all secondary outcomes.

Outcome	Common- τ of the Bayesian model estimated in NMA	Outcome type used as comparator*	Empirical predictive distribution of τ	Location of the estimated common tau compared to the quartiles of the empirical predictive distribution	Judgement of heterogeneity
Dichotomous	Mean (95%CrI)	From Turner et al. ³⁷³	Median (IQR)		
Weight gain (OR)	0.175	Adverse event	0.35 (IQR 0.21, 0.60)	Below 25%-quantile	low
Continuous	Mean (95%CrI)	From Rhodes et al. ³⁶⁶	Median (IQR)		
Fasting Glucose (MD)	1.629	Outcome estimated as mean difference (MD). No comparator available	-	-	-
Fasting glucose (SMD)	0.092	Biological marker	0.16 (IQR 0.06, 0.44)	Between 25%- and 50%-quantile	low-moderate
Total cholesterol (MD)	3.138	Outcome estimated as mean difference (MD). No comparator available	-	-	-
Total Cholesterol (SMD)	0.094	Biological marker	0.16 (IQR 0.06, 0.44)	Between 25%- and 50%-quantile	low-moderate
LDL Cholesterol (MD)	1.947	Outcome estimated as mean difference (MD). No comparator available	-	-	-
LDL Cholesterol (SMD)	0.055	Biological marker	0.16 (IQR 0.06, 0.44)	Below the 25%-quantile	low
HDL Cholesterol (MD)	0.357	Outcome estimated as mean difference	-	-	-

		(MD). No comparator available			
HDL Cholesterol (SMD)	0	Biological marker	0.16 (IQR 0.06, 0.44)	Below the 25%-quantile	low
Triglycerides	8.219	Outcome estimated as mean difference (MD). No comparator available	-	-	-
Triglycerides (SMD)	0.077	Biological marker	0.16 (IQR 0.06, 0.44)	Between 25%- and 50%-quantile	low-moderate

* Intervention comparison type always pharmacological vs pharmacological

16 Discussion of previous reviews

16.1 Pillinger 2020

Pillinger et al.³⁷⁴ conducted a network meta-analysis to compare antipsychotics regarding metabolic side effects occurring in adults with **acute exacerbation** of schizophrenia or related disorders during **acute short-term treatment**. Only randomized double-blind controlled trials were included.

Continuous data of body weight, body-mass index (BMI), and metabolic measures (fasting glucose, total cholesterol, LDL cholesterol, HDL cholesterol, and triglycerides) were analysed.

100 studies (25952 participants) met the inclusion criteria with a treatment duration of 2–13 weeks (median 6 weeks [IQR 6–8]).

In 83 studies with 22960 participants evidence of weight gain was seen for 10 of the 18 antipsychotics with data (antipsychotics with evidence of weight gain compared with placebo: brexpiprazole, asenapine, risperidone and paliperidone, quetiapine, iloperidone, sertindole, olanzapine, zotepine, and clozapine; antipsychotics with no evidence of weight gain compared with placebo: ziprasidone, haloperidol, fluphenazine, aripiprazole, lurasidone, cariprazine, amisulpride, or flupenthixol).

Across all parameters clozapine and olanzapine were associated with the largest degree of metabolic dysregulation.

Additionally, predictors of metabolic dysregulation were examined: Higher baseline weight and male sex were found to predict greater increase in glucose. Non-white ethnicity was associated with greater increases in total cholesterol compared with white ethnicity.

Improvements in symptom severity were associated with increases in weight, BMI, total-cholesterol, and LDL cholesterol, and decreases in HDL cholesterol.

The most important difference to this work is that our network meta-analysis examines mid- to long-term treatment including studies with a duration > 13 weeks weeks. Additional minor differences are that we included studies irrespective of the blinding, examined oral and LAI formulations separately and did not pool risperidone and paliperidone.

16.2 Barton 2020

Barton et al.³⁷⁵ conducted a meta-analysis covering RCTs reporting on antipsychotic induced weight gain with a sample size ≥ 100 , published between 2014 and 2019, irrespective of the diagnosis. They included 27 RCTs (15 of them in individuals with schizophrenia). The included studies focused on **short-term effects** with durations ranging between 3 and 12 weeks. The included antipsychotics were aripiprazole, asenapine, brexpiprazole, cariprazine, lurasidone, quetiapine, olanzapine and risperidone. All compounds led to significant weight gain compared to placebo. Most weight-gain was found for olanzapine followed by asenapine, risperidone, aripiprazole, quetiapine XR, brexpiprazole, cariprazine and lurasidone.

16.3 Spertus 2018

Spertus et al.³⁷⁶ examined 7% weight gain from randomisation in a hierarchical model network meta-analysis with individual patient level data of 3 antipsychotics (olanzapine, paliperidone and risperidone) and placebo. 14 randomized clinical trials (CATIE studies and studies available on YODA) contributing 5923 subjects were examined.

The adjusted odds for weight gain relative to no drug was highest for olanzapine followed by paliperidone and risperidone. An additional analysis of the intensity of exposure revealed a dose-dependent weight increase.

16.4 Zhang 2017

Zhang et al.³⁷⁷ conducted a network meta-analysis evaluating the effect on glucose levels of 12 antipsychotics used for the treatment of schizophrenia and related disorders; 47 RCTs on 9846 individuals (aged from 15 to 65 years) reported the outcome of fasting glucose. The search was limited to January 1995 to June 2016 and only studies reported in English were included. A methodological limitation was that there was no registered protocol for this study.

They found that compared to a placebo only olanzapine was associated with significantly increased glucose levels and olanzapine also showed a significantly greater change in the glucose levels when compared to other antipsychotics (ziprasidone, lurasidone and risperidone).

16.5 Misawa 2016

Misawa et al.³⁷⁸ conducted a meta-analysis of 16 randomized controlled trials including 4902 individuals with schizophrenia or schizoaffective disorder comparing long-acting injectable (LAI) versus oral antipsychotics and found no difference regarding weight change and other metabolic parameters. The only exception was low-density lipoprotein (LDL) cholesterol for which second generation LAIs were associated with significantly greater increases than oral antipsychotics.

16.6 Bak 2014

Bak et al.³⁷⁹ conducted a meta-analysis examining clinical trials of antipsychotics that reported weight change in adults not restricted to the diagnosis of schizophrenia. Body weight change, BMI change, proportion of clinically relevant weight gain and proportion of clinically relevant weight loss were examined. Randomized controlled studies and long-term follow-ups after the end of the study were included. The search included the years 1999 to 2011; 307 articles were included. The evaluation was stratified by the duration of antipsychotic use in four groups (≤ 6 weeks, 6–16 weeks, 16–38 weeks and >38 weeks).

Most antipsychotics showed a statistically significant change in weight postbaseline. Only for amisulpride, aripiprazole and ziprasidone negligible weight change after prolonged exposure was observed. For antipsychotic-naïve patients, a more pronounced weight gain was detected. A significant increase in weight was seen for first-generation antipsychotics and olanzapine when exposure period 4 (>38 weeks) was compared to exposure period 1 (0–6 weeks).

16.7 Zhang 2013

Zhang et al.³⁸⁰ conducted a meta-analysis covering first-episode schizophrenia-spectrum disorders (FES) and compared individual second-generation antipsychotics (SGA) with first-generation antipsychotics (FGA) as a group to evaluate efficacy and safety. The systematic literature search was until December 2010. Acute treatment studies and long-term data from acute RCTs excluding maintenance studies were included, in total 13 studies on 6 second-generation antipsychotics (olanzapine, risperidone, clozapine, amisulpride, quetiapine and ziprasidone). Among others continuous and dichotomous weight gain and changes of glucose, total cholesterol and triglycerides were examined.

Olanzapine and risperidone increased weight significantly more than the comparator first-generation antipsychotics. Clozapine was associated with more weight gain than sulpiride in one study. Pooled SGAs were associated with more weight gain than pooled FGAs. The difference at long-term follow-up between pooled SGAs and FGAs was halved compared to the short-term results. Likewise, weight gain $\geq 7\%$ was significantly more likely with olanzapine and risperidone than haloperidol and with SGAs than FGAs.

Olanzapine, risperidone, amisulpride and quetiapine showed similar glucose changes compared to haloperidol, only ziprasidone was significantly better than haloperidol in one study. Pooled SGAs were similar as FGAs.

Regarding short-term total cholesterol change, olanzapine was significantly worse than molindone and sulpiride and marginally worse than haloperidol. Pooled SGAs were associated with marginally larger total cholesterol increase than FGAs.

Only few studies reported on triglyceride changes and pooled SGAs showed marginally greater short-term triglyceride increase than FGAs.

16.8 De Hert 2012

De Hert et al.³⁸¹ conducted an exploratory meta-analysis limited to four antipsychotics (asenapine, iloperidone, lurasidone and paliperidone) in the treatment of schizophrenia or bipolar disorder and examined mean weight change, 7% weight change compared with pretreatment weight, and change in total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides and glucose.

They found that compared to placebo continuous weight gain was statistically significantly greater for all examined antipsychotics in the short-term. Sufficient long-term data was only available for asenapine and paliperidone showing statistically significant weight gain compared to placebo.

16.9 Rummel-Kluge 2010

Rummel-Kluge et al.³⁸² conducted pairwise meta-analyses on 9 second-generation antipsychotics and 48 studies in total (with an update search in January 2009). For olanzapine and clozapine the highest increase in weight gain was detected with no difference between the substances. Clozapine produced more weight gain than risperidone, risperidone more than amisulpride, and sertindole more than risperidone. A meta-regression of study duration could explain some of the observed heterogeneity with longer studies producing more weight gain than shorter studies; e.g. in short-term studies (≤ 12 weeks) olanzapine produced 2.5 kg more weight gain than ziprasidone, whereas in long-term studies the difference was about 4 kg.

16.10 Meta-analyses on metabolic side effects covering children

Pagsberg et al.³⁸³ conducted 2017 a network meta-analysis of randomized controlled trials of acute antipsychotic treatment in children and adolescents with schizophrenia-spectrum disorders. 12 trials were included with a duration between 6 and 12 weeks covering 8 antipsychotics (aripiprazole, asenapine, paliperidone, risperidone, quetiapine, olanzapine, molindone, and ziprasidone). All tested antipsychotics showed more weight gain than placebo, except for molindone and ziprasidone. Weight gain was found to be primarily associated with olanzapine.

Kumar et al.³⁸⁴ conducted 2013 a Cochrane review with meta-analysis of 13 RCTs examining atypical antipsychotics for psychosis in adolescents. Treatment with olanzapine, risperidone and clozapine was often associated with weight gain.

Almandil et al.³⁸⁵ performed 2013 a meta-analysis including double-blind, randomized controlled trials investigating metabolic adverse effects (weight gain, lipid, glucose, and prolactin level abnormalities) associated with atypical antipsychotic use in children and adolescents aged ≤ 18 years irrespective of the diagnosis. They included 14 studies for risperidone (1331 patients), three for olanzapine (276 patients), and four for aripiprazole (848 patients). The majority of trials lasted less than 10 weeks. Compared with placebo, the mean weight increases for each drug were olanzapine 3.45 kg (95 % CI 2.93–3.98), risperidone 1.77 kg (95 % CI 1.35–2.20), and aripiprazole 0.94 kg (95 % CI 0.65–1.24).

Cohen et al.³⁸⁶ conducted 2012 a meta-analysis of short-term (up to 12 weeks) controlled trials on adverse effects associated with second-generation antipsychotics in children and adolescents irrespective of the diagnosis. Dichotomous weight gain was reported by 25 studies (62 arms, 3401 participants). Odds ratios for risk of weight gain ranged from 3.77 (CI 0.37 to 16.27) for ziprasidone to 15.1 (CI 6.56 to 31.1) for olanzapine. Mean weight gain ranged from 0.89 to 3.99kg (30 studies, 66 arms, 3221 participants) and was highest for olanzapine (mean gain 2.99kg). Ziprasidone was associated with a mean weight loss of -0.1kg, which was not statistically significant.

Pringsheim et al.³⁸⁷ conducted 2011 a meta-analysis of 35 double-blind, randomized controlled trials (RCTs) of SGA conducted in children with mental health disorders. They found that mean weight gain compared with placebo was highest for olanzapine at 3.47 kg (95% CI 2.94, 3.99) followed by risperidone at 1.72 kg (95% CI 1.17, 2.26), quetiapine at 1.41 kg (95% CI 1.10, 1.81) and aripiprazole at 0.85 kg (95% CI 0.58, 1.13). The majority of trials lasted 10 weeks or less.
